Serial No.	Date of Issue.	Journal Pages.	Supplement Pages.
3600	Jan. 4th	1 – 54	1 – 8
3601	,, 11th	55 – 96	9 – 16
3602	,, 18th	97 – 134	17 – 24
3603	,, 25th	135 – 180	25 – 32
3604	Feb. 1st	181 – 226	33 – 36
3605	,, 8th	227 – 268	37 – 44
3606	,, 15th	269 – 320	45 – 56
3607	,, 22nd	321 – 372	57 – 64
3608	March 1st	373 – 428	65 – 68
3609	,, 8th	429 – 478	69 – 76
3610	,, 15th	479 – 524	77 – 88
3611	,, 22nd	525 – 576	89 – 96
3612	,, 29th	577 – 628	97 – 100
3613	April 5th	629 – 676	101 – 108
3614	,, 12th	677 – 726	109 – 120
3615	,, 19th	727 – 768	121 – 164
3616	,, 26th	769 – 806	165 – 200
3617	May 3rd	807 – 848	201 – 208
3618	,, 10th	849 – 892	209 – 220
3619	,, 17th	893 – 936	221 – 228
3620	,, 24th	937 – 986	229 – 236
3621	,, 31st	987 – 1032	237 – 244
3622	June 7th	1033 – 1080	245 – 256
3623	,, 14th	1081 – 1118	257 – 268
3624	,, 21st	1119 – 1160	269 – 284
3625	,, 28th	1161 – 1204	285 – 292

INDEX TO VOLUME I FOR 1930.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, *X* Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Correspondence," "Leading Articles," "The Week," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

Abattoirs, public, 40
Abdominal pain, localization of (V. Zachary Cope), 895 (O)—Correspondence on, 973. *See also* Pain
Abdominal surgery at sea, 268. *See also* Surgery
Aberdeen. *See* Scotland
ABLETT, Richard: *A Course in Physics for Medical and Dental Students*, rev., 501
Abortion, epizootic, 963. *See also Brucella abortus*
Abortion, natural, causes of, 44
Abortus fever (J. Norman Cruickshank and Robert Cruickshank), 195 (O)—(James S. Baxter), 861 (O). *See also* Fever
ABRAHAMS, Adolphe: High blood pressure, 742—Physical and mental aspects of the Jews, 1052
ABRAHAMSON, Leonard: Toxic goitre, 595
ANDER, Sir G. Stewart, memorial window to, 178
Abscess, alveolar, death following (P. Digby Griffiths), 1173
Abscess of the brain (Heinrich Neumann), 237
Abscess of the brain with unusual features (E. G. Collins), 438 (O)
Abscess, cerebral, of unusual etiology (T. G. Wilson), 546
Abscess of lung, treatment of (F. G. Chandler), 445—Discussion at Royal Society of Medicine, 445
Académie de Médecine: Prizes awarded by, 178—The B.C.G. controversy, 236
Académie des Sciences awards prizes to French medical men, 133, 676
Academy of Medicine, Flemish, proposed, 1148

ACADEMY, ROYAL, OF MEDICINE, IN IRELAND
Section of Anatomy and Physiology.—Cresoluris, 864
Section of Medicine.—Myelopathic albumosuria, 446—Xanthoma *tuberosum multiplex*, 446—Persistent pneumothorax, 446—Lupus vulgaris treated by radiotherapy, 446—Splenectomy in splenic anaemia, 697—The significance of achlorhydria, 638—Lipoid *nephrosis*, 953—Atypical meningitis, 1177—Spirochaetal jaundice, 1178
Section of Obstetrics.—Uterine malignancy, 333—Uterine haemorrhage of doubtful etiology, 333—Acute uterine inversion, 394—Caesarean hysterectomy, 534, 594—Work of the Rotunda Hospital, 1048
Section of Pathology.—Hodgkin's disease, 200—Oriental sore, 201—Gummata of [illegible] 200—Leucosarco[illegible] unusual etiol[illegible] breast, 546—Empyema due to *Gaertner's* bacillus, 546—Paget's disease of the breast, 1095—Malignant disease of the thyroid, 1096—Cerebral thrombosis and aneurysm, 1097
Section of State Medicine.—Illumination and print, 244
Section of Surgery.—Free perforative diverticulitis, 18—Principles of radium therapy, 18—Spinal cord tumour, 493—Transplantation of external biliary fistula, 493—Hydatid cyst of liver, 499—Toxic goitre, 534—Anaesthetic screen for thyroidectomy, 534—Chloroform for pain, 825—O[illegible] 825—Hairy or d[illegible] neuroma, 826—Reduplication of renal pelvis, 1134—Fibroma in the knee-joint, 1134—Calcification of kidney, 1134

Accidents, review of book on, 1097
Accidents: Road traffic [illegible] 50, 222,
A[illegible] the Bill
A[illegible] ...inal fluid,
[illegible] ...ry Moorel), 693
arising from
Acta Medica Scandinavica, [illegible] a-
tion[illegible] id
oxyg[illegible] m
(Gu[illegible] m
Epi[illegible] m
Acta Paediatrica: The development of premature infants, 251
Actinomycosis common to man and animals: Discussion at the Royal Society of Medicine, 199
Actinomycosis of the tonsils (Vernon Smith), 148
Actinotherapy (Percy Hall), 149
"Activated" fluorescein. *See* Fluorescein
ACWORTH, Commander Bernard: *This Bondage: A Study of the "Migration" of Birds, Insects, and Aircraft, with some Reflections on "Evolution" and "Relativity,"* rev., 291
ADAMI, Marie: *J. George Adami*, rev., 101
ADAM, John: Hypochlorhydria of asthma, 1139
ADAMS, A. Wilfrid: Death during spinocain anaesthesia, 760
ADAMS, H. Percy, obituary notice of, 802
ADAMSON, Rt. Hon. William: Mental welfare in Scotland, 922
Adder bite (Mark R. Taylor), 337 (O)
ADDISON, Christopher, appointed Minister of Agriculture and Fisheries, 1106
ADLER, Alfred: *The case of Miss R.*, rev., 341
Administration, some aspects of (Lieut.-Col. M. B. H. Ritchie), 316
Adolescent, education of the, 161
Adolescent, review of book on the, 866
Adrenaline and asthma, 1110
AEBERLY, Dr.: Methyl chloride poisoning, 731
AFFLECK, R. Cunningham: Sequelae of *Brucella abortus* infection in man, 1075
Africa, East: Malaria in (leading article), 207—Correspondence on, 372
Africa: *The South and East African Year Book and Guide*, rev., 655
Africa, West: *West African Medical Staff List*, total strength of officers on, 130
AGNEW, Harvey: Noise in hospitals, 730
Agra: Health measures in, 168
Agricultural Research Conference, Imperial: Food preservation and transport, 834
AINSWORTH-DAVIS, J. C. (and T. P. DUNHILL): Renal calculus associated with a solitary cyst of left kidney, 10 (O)
Air cushion for colostomy patients, 116
Air, effects of on the vascular system, and the [illegible] ...sis
[illegible] ...ers
Air passages, foreign bodies in (T. Guthrie), 333
AL, Abdul, O.B.E. conferred on, 1058
ALABASTER, G. H.: The conduct of normal midwifery in relation to puerperal sepsis, 128
ALABY, Dr., appointed professor of surgical [illegible] rand, 179
[illegible] ,849
[illegible] (A. R. Parsons, [illegible] gham, and J. Lait),
Alcoholism, recent literature on (J. D. Rollestor), 1118
Alcoholism, psychotherapy in (William Brown), 152
ALEXANDER, Frederick William: Treatment of pruritus ani, 1160
ALEXANDER, G. F.: Modified capsule forceps, 774
ALEXANDER, H. G.: *Narcotics in India and South Asia*, rev., 443
Alimentary diseases, review of books on, 1135
Alkaloids, review of book on the chemistry of, 501
ALLAN, Mary (and N. Gray HILL): Family incidence of juvenile rheumatism, 949 (O)
ALLAN, R. Marshall, appointed to the chair of obstetrics in the University of Melbourne, 36
ALLBUTT, Sir Thomas Clifford: Preparation of scientific papers, 29
ALLEN, A. G.: Spinal anaesthesia, 495
ALLEN, A. H. Burton: *Pleasure and Instinct*, rev., 744
ALLEN, F. J.: Foxglove at the bedside and elsewhere, 283—Appreciation of Jamieson Boyd Hurry, 475—Treatment of tachycardia, 892
ALLEN, I. M.: Congenital word-blindness, 454
Allen's Commercial Organic Analysis. Vol. vii, *The Vegetable Alkaloids*, rev., 511
Alopecia areata, review of book on, 205
ALTOUNYAN, E. H. R.: Lipiodol injections into the bronchi, 719
Ambulance Association, St. John, extension of the work of in Canada, 725
Ambulance Service, Home: Report, 734, 1107
Ambulance service, London, to come under the London County Council, 454
America. *See* United States
America as seen by a scientist (J. W. Bigger), 355
Amidopyrin in the treatment of measles (J. L. Collier), 1093 (O)
Amputations and their relation to the artificial limb (C. Max Page), 693—Leading article, 705—Correspondence on, 841, 881, 939
Anaemia, pernicious, hog's stomach in treatment of (Arnold Renshaw), 334 (O)
Anaemia, pernicious, production of in albino rats by deficient feeding (Lucy Wills and Maneck M. Mehta), 1157 (O)
Anaemia, pernicious, report on the treatment of with certain preparations of stomach (John F. Wilkinson), 236 (O)—(Arnold Renshaw), 334 (O)
Anaemia, pernicious, review of book on, 903
Anaemia, splenic, *splenectomy in* (F. X. Calleghan), 697
Anaemia, trauma and sepsis in the causation of, 835
Anaesthesia, avertin, in *laryngology* (W. Thacker Neville), 1175
Anaesthesia, deaths from, 847, 1233
Anaesthesia, ethylene (R. J. Clauson), 852—Discussion, 853
Anaesthesia, explosion hazard in: Report of committee of the American Medical Association, 1062
Anaesthesia, local, technique of (J. R. Griffith), 72
Anaesthesia, paraldehyde before (Hugh R. Phillips), 279 (O)—Correspondence on, 1112
Anaesthesia, regional, experiences with (H. W. L. Molesworth), 13 (O)
Anaesthesia, review of books on, 545, 955
Anaesthesia for short operations on children, especially tonsillectomy (H. Marcus Bird), 147 (O)—Correspondence on, 217, 252, 313, 362, 416, [illegible] ...Anaesthesia
[illegible] (B. A. Grant),
Anaesthesia, spinal, eclampsia treated with (B. H. Paramore), 15 (O)
Anaesthesia, spinal, in midwifery (Dr. Hunter), 1051 (J. W. Burns), 1051
Anaesthesia, spinal, with percain (Howard Jones), 425
Anaesthesia, spinal, review of book on, 545
Anaesthesia, spinal, with spinocain (Charles Donat), 495—Discussion, 495
Anaesthesia, spinocain, death during (A. B. Hudson), 695, 930—(A. Wilfrid Adams), 760—(C. L. Granville Chapman), 799
Anaesthesia in thoracic surgery (C. Langton Hewer), 235
Anaesthesia, tongue tied for, 72
Anaesthesia for tonsillectomy (H. Marcus Bird), 147 (O)—Correspondence on, 217, 252, 313, 362, 416, 467, 518, 553, 619, 1022, 1154. *See also* Anaesthesia for short operations
Anaesthetic, a new local (percain), 155—(Norman C. Lake and C. Jennings Marshall), 423 (O)—(Howard Jones), 495—Discussion, 495—Correspondence on, 669
Anaesthetics in midwifery, 220, 414, 468, 517, 569, 619, 718, 759—Fund for, 220, 569
Anaesthetics administered by midwives (parliamentary note), 472
Anaesthetics, review of books on, 597, 654
Anaesthetics, safe administration of (William Fulde), 553
Anal fissure. *See* Fissure
Analysis, review of books on, 115, 501
Anaphylaxis *following injection* of pituitary extract (James Hasson), 242
Anatomical illustrations, exhibition of, 1062
Anatomy, orthodox and heterodox, in relation to surgery (W. McAdam Eccles), 373 (O)—Leading article, 404
Anatomy, review of books on, 242, 743
Anatomy, teaching of (leading article), 434—Correspondence on 513, 833

ANDERSON, A. Greig: Case of gross myxoedema, 535
ANDERSON, D. Drysdale: A disclaimer, 576
ANDERSON, Dorothy M.: Mixed *Brucella* infection, 975
ANDERSON, J. Barcroft: Genetic relationships, 226—Pellagra, 1050
ANDERSON, R. E.: Two cases of axillary breast, 283
ANDERSON-STUART, Surgeon Lieut.-Commander Archibald Primrose, obituary notice of, 418
ANDREW, K. M.: Flea infestation, 1031
Aneurysm, aortic, simulating asthma (L. G. Hill), 1048—Correspondence on, 1118
Aneurysms, multiple (S. Alec Grant), 494
ANGERER, Karl von, appointed professor of hygiene at Erlangen, 477
Angina pectoris treated by muscle extract (M. S. Schwartzman), 855 (O)—Correspondence on, 1073
Aniline workers, cancer of bladder in (parliamentary note), 1157. *See also* Cancer
Animal disease research: In Edinburgh, 255—Parliamentary notes, 266 890—At Cambridge, 890
Animal products, list of, 248
Animals, domestic, diseases of from the human standpoint (O. C. Bradley), 1182
Animals, living, experiments on (parliamentary note), 52, 574, 626, 1157—At Porton, 765
Ankles, swelling of, not associated with albuminuria or gross organic disease (A. Arnold Osman), 780 (O)—Correspondence on, 928, 986
Ankylostomiasis, review of book on, 865
Announcements of forthcoming events, etc., 53, 94, 132, 178, 224, 265, 370, 426, 476, 523, 574, 627, 675, 725, 767, 805, 846, 891, 935, 984, 1030, 1078, 1117, 1158, 1202
Ante-natal work in Monmouthshire, 805
Ante natal, natal, and post-natal problems (W. H. F. Oxley), 275 (O)
ANTHONY, Major-General R. W.: Indian Medical Degrees, 797
Anthracosis (parliamentary note), 1028, 1157. *See also* Silicosis
Anthrax, cutaneous (A. E. Hodgson), 596
Anthrax, deaths from (parliamentary note), 426, 1028—*Disinfection of hides and skins* (parliamentary note), 765
Anthropometry, review of book on, 909—Correspondence on, 1023
Anthropometry, school, 1023
Antidote bag, 956
Antimalarial measures, 207, 259, 372, 518, 718, 797, 840, 886, 928, 1151. *See also* Malaria
Antirabic treatment in India, progress of, 923. *See also* Rabies
Antitoxin, scarlet fever, passive immunization by means of (James M. Cowie), 588 (O)
Antitoxins, specific, in streptococcal infection (Herbert H. Brown), 1092 (O)
Antivivisection mare's-nest (parliamentary note), 1157
Antwerp, tropical diseases exhibit at, 750
Aortic aneurysm. *See* Aneurysm
Aortic stenosis, case of (W. Harvey Bennett), 948 (O)
Aortitis, syphilitic (Erich Leschke), 652
Aphonia, dysphonia, and the "singer's attitude" (Sir James Dundas-Grant), 539 (O)
Aphonia, treatment of (E. C. MacLeod), 392
Apothecaries' Society of London: Degrees and pass lists, 52, 224, 418, 627, 845, 1027, 1202—Yeomanry dinner, 83—Appointment of Registrar, 1158
Appendicitis, acute, complicated with paratyphoid fever (Lieut. J. F. Wilde), 16
Appendicitis, acute, an important sign in (F. W. Sumner), 106 (O)
Appendicitis, acute, Ochsner-Sherren (delayed) treatment of (Hamilton Bailey), 140 (O), 216—A correction, 216—Correspondence on, 216, 260
Appendicitis, chronic, or appendix dyspepsia (H. F. Woolfenden), 393
Appendicitis, operations for (Stanley Raw), 483 (O)
Appendicitis simulated by dysentery, 806
Appendicitis, syphilitic, acute (Griffith Evans and Elwyn Rowlands), 11 (O)
Appendix, cancer of. *See* Cancer
Appendix, diseased, radiological diagnosis of (A. Orliansky), 330 (O)
APPERLY, R. E.: Anaesthesia in thoracic surgery, 287—Spinal anaesthesia, 496
APPLETON, A. B.: *Laboratory Guide to Vertebrate Dissection*, rev., 248
Aptitude tests for medical students, 833
ARCHER, Dr.: Zondek-Aschheim test for pregnancy, 151
Argentine Republic, psittacosis in, 458
ARGYLE, Hon. Stanley Seymour, K.B.E. conferred on, 30
ARKWRIGHT, Surgeon Commander Eustace, obituary notice of, 130
Arm, a borrowed, 806
ARMIT, Henry William: *Obituary notice of, 570*—Appreciation of in the *Medical Journal of Australia*, 985
ARMOUR, Donald: Cardiac infarction, 542
ARMSTRONG, John: *Death following tonsillectomy*, 39
ARMSTRONG, R. R.: Puerperal infection, 925
ARMSTRONG-JONES, Sir Robert: Henderson Trust Lecture on the growth of the mind published in pamphlet form, 95—Psychotherapy in alcoholism, 152—Psychiatry in America, 741
ARMY BRITISH:
Estimates, 672, 722
Golf meeting, 266
Health of: Report for 1928, 304
Medical officers in (parliamentary note) 674

ZOELLER, C., appointed professor of epidemiology and bacteriology at the Val-de-Grâce School of Military Medicine, Paris, 805
Zondek-Aschheim test for pregnancy (J. H. Hannan), 150—Discussion at Royal Society of Medicine, 150—Correspondence on, 217
Zoology, review of books on, 655, 744
ZUR VERTH, Max (Reinhold RUGE, and Peter MÜHLENS): *Krankheiten und Hygiene der Warmen Länder*, third edition, rev., 247

LIST OF ILLUSTRATIONS.

SPECIAL PLATES.

		PAGE
Appendicitis, Acute Syphilitic (G. Evans and E. Bowlands)	facing	11
Atelectatic Bronchiectasis (A. J. S. Pinchin and H. V. Morlock)	facing	11
Bone-graft, Hinged (Arnold K. Henry)	facing	737
Branchial Cleft, Patent (A. H. G. Johns)	facing	1045
Carcinogenic Substances and Their Fluorescence Spectra (E. L. Kennaway and I. Hieger)	facing	1045
Diverticulitis (W. H. Bowden)	facing	381
Dystrophy of Nails, Congenital (F. A. E. Silcock)	facing	1045
Excretion Urography (Kenneth Heritage and R. Ogier Ward	facing	736
Fractured Pelvis (N. H. Lindsay)	facing	737
Fractures, Union and Non-union of (A. S. Blundell Bankart)	facing	10
Gall-bladder Lesions and Hepatitis (E. B. Flint)	facing	1044
Needling, Retrograde (K. H. Pridie)	facing	380
Phthisis, Diagnosis and Treatment of (W. A. Dickson)	facing	330
Pulmonary Cavities, Pathogenesis of (S. Vere Pearson)	facing	380
Renal Calculus with Solitary Cyst of Left Kidney (J. C. Ainsworth-Davis)	facing	10

ILLUSTRATIONS IN THE TEXT.

	PAGE
Air Cushion for Colostomy Patients	116
Anaemia, Pernicious, Production of in Rats (Lucy Wills and Maneck M. Mehta)	1167
Anal Fissure Treated by Diathermy (Frank Howitt)	1169
Anatomy in Relation to Surgery (W. McAdam Eccles)	374
Antidote Bag	956
Aortic Stenosis (W. Harvey Bennett)	948
Appendix, Diseased, Radiological Diagnosis of (A. Orliansky)	330
Bed Foot-rest	342
Bed Frame, Reversible, for Spinal Cases (Ernest W. Hey Groves)	66
Blood Trail (Sir John Bland-Sutton)	938
Bone-graft, Hinged (Arnold K. Henry)	738
Bone-plating, Retractors for	910
Boobbyer, Philip	221
Bowman, Sir William	701
Bridges, Robert	801
Cancer, Primary, of Appendix (E. W. M. H. Phillips and Donald H. Isaac)	1127
Cancer Treated by Radiation (Sir G. Lenthal Cheatle)	810
Cardiac Failure, Early Signs of (Sir Thomas Lewis)	850
Cholecysto-colic Fistula (C. J. Fuller)	220
Cirrhosis of Liver, Operative Treatment of (Thomas Tannahill)	281
Coronary Disease and Sudden Death (C. E. K. Herapath and C. B. Perry)	685
Coronary Occlusion (Crighton Bramwell)	682
Diverticulitis of Colon, Perforative (Sir W. L. de Courcy Wheeler)	6
Drill for Patella Suturing	205
Electro-cardiograph in Acute Myocarditis (Donald Hall)	1046
Electro-cardiograph, Portable (J. Strickland Goodall and T. Jenner Hoskin)	107
Erythrocyte, Human, Structure of the (W. E. Cooke)	434
Ether Inhaler, Open	1099
Forceps, Capsule, Modified	744
Forceps, Tonsil-holding	292
Foreign Body, a Historic (T. B. Layton)	24
Foreign Body in Right Bronchus of a Baby (V. Smallpeice)	69
Fripp, Sir Alfred Downing	473
Fry, Hubert John Burgess	931
Gangrene, Symmetrical, Complicating Rheumatoid Arthritis (Ralph Brooke)	493
Gastric and Duodenal Ulcer, Treatment of (Charles Bolton)	730
Greaves, Francis Ley Augustus	843
Hayes, Maurice Richard Joseph	519
Head Mirror, an Adjustable	1038
Hempson, William Ernest	314
Hempstead Church before 1832	23, 296
Hernial Sac, Strips of Fascial Sutures (F. B. Brown)	858
Hickman, Henry Hill	713
Ileus: Acute and Paralytic (H. Tyrrell-Gray)	1161
Inhaler, Modified Ogston's	766
Kümmell's Disease (S. Watson-Smith)	110
Laryngeal Mucus Extractor	829
Ligature Holder, an Improved	655
Martin, Albert Morton	177
Martin, James Hogg	131
Melanotic Sarcoma, Spontaneous Inoculation of (F. Parkes Weber, E. Schwarz, and R. Hellenschmied)	537
Milligan, Sir William	47
Needling, Retrograde (K. H. Pridie)	380
Ochsner-Sherren Treatment of Appendicitis (Hamilton Bailey)	141
Oesophageal Intubation, Simple and Safe Method of (Courtenay Yorke)	440
Operations on Infants, an Aid to	548
Osteitis Deformans (Clement Nicory)	492
Ovarian Cyst, Twisted, in a Child (R. C. B. Macrae)	996
Oxygen Inhaling Apparatus, Portable	22
Patella Suturing, Drill for	205
Pharyngoscope, Modified Hay's	292
Pregnancy, Ruptured Ovarian, Case of (E. L. Graff)	902
Prostatectomy Incising Clamp	116
Prostatic Obstruction (Kenneth M. Walker)	812
Pyelography, Intravenous (E. J. H. Roth and H. W. S. Wright)	778
Radium Needle Introducer	75, 1055
Radium Needle, Safety	292
Radium Teletherapy (Francis Rock Carling)	232
Radon Seed Depositor	1137
Raspatory, Farabeuf's, Modified Form of	248
Sterilizer, Electric, Simple and Inexpensive	75
Suturing, Surface, Emergency Method	205
Thane, Sir George Dancer	175
Thermostat for Blood Transfusion, Portable (Geoffrey Shera)	904
Tongue Blade for Anaesthesia	22
Tonsil Pressor	22
Tubby, Alfred Herbert	419
Tuberculous Knees Treated by the Cautery (A. Z. C. Cressy)	857
Urine, Retention of (H. J. McCurrich)	192
Vaginascope	248
Varicose Vein Clip, a New	156
Winnipeg and District, Views of	31, 300, 557, 875, 1054
Wynne, Frederick Edward	842

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1930.

F. W. W. GRIFFIN, M.D.,
SUB-EDITOR.

London:
PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME I, 1930.

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

Abdominal incision after Caesarean section, rupture of the, 91
Abortion: *Br. abortus* in human pathology, 252
Abortion, undulant fever in, 251
Abscess of lung following tonsillectomy, 558
Abscess, mammary, simulating cancer, 61
Abscess, prevesical, in pregnancy, associated with asthma, 408
Abscess of prostate, acute, 133
Acacia in obstetrical shock, 26
ACHARD, C.: Nephritis with hypochloraemia, 323
Achylia, blood examination in, 273
Acid-alkali treatment of urinary infections, 39
Acidosis, post-anaesthetic, 120
ADAMS, L. J.: Tuberculosis of the aorta, 98
ADAMY, G.: Psittacosis, 257
Adder bite, serum treatment of, 477
Adenitis treated by diathermy, 324
Adnexa, healthy, volvulus of, 437
Adnexa, uterine, torsion of, 386
Adnexal inflammation, chronic, treatment of, 313
Adonidine as a cardiac diuretic, 330
Adrenaline and angina pectoris, 447
Aertrycke infection, 556
Age distribution of normal antibodies in man, 94
Agranulocytosis following antisyphilitic treatment, 393
Alcohol, concentrated, orbital injections of for the relief of ocular pain, 213
Alcohol injections: In thoracic surgery, 232—Intravenous for general anaesthesia, 513, 544
Alcoholism: Epilepsy and, 34—And nervous diseases, 417
ALFANDARY: Tumours of the fourth ventricle, 147
ALLEN, E.: Time of ovulation in the menstrual cycle, 589
Allergy, ability of formolized vaccine to give rise to, 346
Alopecia areata, 44
ALTSCHULE, M. D.: Ethyl iodide inhalations, 332
AMAN-JEAN, F.: Treatment of glandular epitheliomata, 496
Amniotic band strangulating the cord, 290
Anaemia from haemorrhage, bone marrow in, 400
Anaemia, liver treatment of, 361, 584
Anaemia neonatorum, 286
Anaemia, pernicious, in a boy, 227
Anaemia in pregnancy, 220, 247
Anaemia, reticulocyte reaction in, 31, 487
Anaemia, secondary, in pregnancy and the puerperium, 247
Anaemia of splenectomized rats, 488
Anaemias, chronic idiopathic secondary, 156
Anaesthesia, colonic, 20
Anaesthesia, death during *induction of*, 243
Anaesthesia, ether: In children, 22—Intratracheal, 122
Anaesthesia, ethylene-oxygen, intratracheal, 21
Anaesthesia, general, by intravenous alcohol injections, 513, 544
Anaesthesia, infiltration, in fractures, 457
Anaesthesia during labour in private practice, 344
[illegible] 460
[illegible] in tonsil-
Anaesthesia, novocain, in gynaecology, 246
Anaesthesia, rectal, with avertin, 542
Anaesthesia, regional, in urology, 353
Anaesthesia, spinal, 23, 245, 453, 459—In abnormal labours, 124—Spinocain in, 244—With gravity solutions, 545
[illegible] nino-
[illegible] sul-
Anatoxin prophylaxis against diphtheria, 203, 574, 575
ANDERSON, R. J.: Chemistry of the lipoids of tubercle bacilli, 413
Aneurysm of [illegible]
Angina, Vincent's [illegible] And fuso-spiro[illegible]
Angior[illegible]
Angior[illegible]
Animals, young and old, antigenic differences between the serums of, 130
Anthrax, transmission of, 350
Anti-asthmatic drugs, 540
Antibodies in man, normal, age distribution of, 94
Antibody absorption, specific, by the viruses of vaccinia and herpes, 523
Antigangrene serum in typhoid fever, 42
Antigenic differences between the serums of young and old animals, 130
Antisyphilitic treatment: Jaundice during, 105—Followed by agranulocytosis, 393
Antityphoid inoculation in children, 181
Aorta: Coarctation of the, 288—Tuberculosis of the, 98
APITZ, G.: The salt-free diet in tuberculosis, 167
Aponeurotic sclerema. *See* Sclerema
APPELBAUM, E.: Autogenous vaccine therapy in meningococcal meningitis, 455
APPELMANS, R.: Chronic duodenal stenosis, 535
Appendicitis and pyosalpinx with a vesical fistula, 579
Appendicitis, influenzal, primary, 38
Appendix, vermiform, carcinoid of the, 230
ARCIERI, N.: Novacain anaesthesia in gynaecology, 246
ARONS, I.: Sarcoma of the thyroid gland, 260—Combined radium and x-ray therapy in rectal carcinoma, 564
Arrhythmia in children, digitalis as a cause of, 561
Arsenobenzenes in syphilis, 304
Artery, iliac, embolectomy of left external, 495
Artery, innominate, traumatic rupture of, 207
Artery, splenic, rupture of aneurysm of the, 58
Arthritis, electrical treatment of, 566
Arthritis, endocrine, 276
ASHEBSON, N.: The radium dosage for menorrhagia, 219
Asphyxia, traumatic, 396
Asthma: Associated with prevesical abscess in *pregnancy*, 408—*Emphysema* (subcutaneous) in, 77
Asthma, bronchial, complicated by pulmonary atelectasis, 535
Atelectasis: Pneumonic, carbon dioxide inhalation in, 264—Pulmonary, complicating bronchial asthma, 535
Athletic strain *and the heart*, 317
AUBERTIN, Ch.: Late sequels of cardiac infarction, 97—Established hypertension without cardiac hypertrophy, 132—Agranulocytosis following antisyphilitic treatment, 393
AUBERTIN, E.: *Laboratory tests* of B.C.G., 176—The protective power of B.C.G., 551
AUDRY, C.: *Benign* aponeurotic sclerema, 405
Auricular contraction, accessory, in Stokes-Adams syndrome, 352
Auricular fibrillation, action of digitalis in, 115
Auto-blood transfusion in *gynaecology*, 25. *See also* Blood
Autogenous vaccine therapy in meningococcal meningitis, 455
Avertin in rectal anaesthesia, 542
Avitaminosis C and experimental infection, 439
AYNESWORTH, K. H.: Ptosis of the colon, 12
AYNSLEY, T. R.: Buphthalmos and naevus, 65
AZAM, A.: Benzo-meta-cresol in intestinal infestations, 493
AZNAR, P.: Antigangrene serum in typhoid fever, 43
Azotaemia in urinary diseases, 5

B.

Babinski's sign in the newborn, 35
BABONNEIX, L.: Congenital syphilitic spastic paraplegia, 385
BACCARANI, U.: Chronic non-calculous cholecystitis, 302
BACH, O.: The sedimentation rate during the climacteric, 508
Bacilluria during pregnancy and the puerperium, 462
Bacillus Calmette-Guérin, laboratory tests of, 176—The protective power of B.C.G., 551
Bacillus diphtheriae causing varicella gangrenosa, 469
Bacillus of dysentery: Separation of from typhoid bacillus by motility, 440—Epidemiological types of in Denmark, 443
Bacillus enteritidis, meningitis due to, 469
Bacillus of leprosy, cultivation of, 52
Bacillus of tubercle: In laryngeal smear preparations, 371—Chemistry of the lipoids in, 413—Filterable elements of the, 573. *See also* Tubercle
Bacillus of typhoid, separation of from bacillus of dysentery by motility, 440
Bacillus typhosus Type G, 571
Bacteriophage filtrates, the use of, 497
Bacteriophage treatment of typhoid fever, 519
Bacterium enteritidis Gaertner, *toxin formation by*, 315
BAILEY, K. V.: The terminology of cervical erosion, 461
BAILLY, J.: Experimental tuberculosis infection by the nose, 202
BAJ, L.: Experimental infection and avitaminosis C, 439
BANG, O.: Prophylaxis of measles with serum of convalescents, 539
Banisterin in post-encephalitis, 193
Banti's disease cured by splenectomy, 236
BARBET: Appendicitis and pyosalpinx with a vesical fistula, 579
BARGEN, J. A.: Carcinoma of the colon, 60
BARLOW, O. W.: Anti-asthmatic drugs, 540
BARNES, A. R.: Inversion of the T-wave in ventricular strain, 1
BARRÉ, J. A.: Tumours of the fourth ventricle, 147
BARRON, M. E: Thrombo-angiitis obliterans, 10
Basal metabolism: In heart disease, 204—And emotional states, 502
BASCH, G. (and Marianne BASCH): Primary meningitis and meningo-encephalitis in mumps, 318
BASSET, A.: Regional vaccine therapy in salpingitis, 525
BAUER, A. W.: Treatment of chronic adnexal inflammation, 313
BAYER, W.: Treatment of pyloric spasm in infants, 335
BAYLIS, Adelaide B.: Spontaneous tuberculosis in guinea-pigs, 177
BAZIN, J.: Encephalomyelitis in the fox, 532
BECKER, J.: Congo red as a haemostatic, 499
BEER, E.: Total cystectomy for bladder carcinoma, 9
BEGLE, H. L.: Perforating injuries of the eye, 216
BEHMANN, H.: Tubercle bacilli in laryngeal smear preparations, 371
BEHNEY, C. A.: Ovarian transplantation, 70
BELL, G. H.: Iridotasis for primary and secondary glaucoma, 483
Belladonna in sea-sickness, 191
BENEDETTI, P.: Massive collapse of the lung, 33
BENZION, I.: Conduct of the third stage of labour, 93
Benzo-meta-cresol in intestinal infestations, 493
BERG, S.: Serum lipase and tuberculosis, 96
BERGGLES, B.: Surgical treatment of typhoid carriers, 471
BÉRIEL, L.: Pott's disease and intraspinal tumours, 397
BERINGER, K.: Harmine (or banisterin) in post-encephalitis, 193
BERNARD, R.: Retention of dead ectopic foetus, 547
BERNHARDT, H.: Combined radiation treatment of malignant growths, 450
BERTRAND, P.: Rupture of aneurysm of the splenic artery, 58
BICKEL, G.: The association of pulmonary gangrene and tuberculosis, 205
BIE, V.: Antitoxin in diphtheria, 518
Bile ducts, congenital obliteration of the, 399
BIRNBAUM, G. L.: *Carbon dioxide inhalation in pneumonic atelectasis*, 264
Birth-marks as a site for vaccination, 259
Bismuth, lipo-soluble, in the treatment of syphilis, 380
Bismuth therapy in congenital syphilis, 380
Blackwater fever. *See* Fever
Bladder, endometriosis of the, 269
BLANC, H.: Azotaemia in urinary diseases, 5
BLAND, L. J.: Time of ovulation in the menstrual cycle, 589
BLAND, P. B.: Secondary anaemia in pregnancy and the puerperium, 247—Sedimentation test in pregnancy, 454

Blood, acid-base equilibrium of in acute rheumatism, 29
Blood, bactericidal action of, resistance of haemolytic streptococci to, 274
Blood, coagulation rate of, determination of, 445
Blood diastase after operations on the stomach, 200
Blood groups in Shansi, 592
Blood, human: Bactericidal power of in typhoid fever, 30
Blood, menstrual, passage of through the Fallopian tubes, 387
Blood picture in varicella, 349
Blood, splenic opotherapy, effects of on the, 370
Blood, thyroid and lipoid content of the, 316
Blood transfusion: Auto-blood transfusion in gynaecology, 25
BLOOMBERG, W.: Potassium sulphocyanate in hypertension, 18
BLUMGART, H. L.: Ethyl iodide inhalations, 332
BOAS, H.: Pregnancy and labour in congenital syphilis, 528
BOCK, G.: Age distribution of normal antibodies in man, 94
BOCTOR, W.: Spinal anaesthesia, 23
BOHEC, J.: Belladonna in sea-sickness, 191
BOHÊME, P.: Congenital malformation of the ileo-caecal valve, 187
BOINE, J.: Chronic duodenal stenosis, 536
BOISSERIE-LACROIX: Treatment of diabetes insipidus by pituitary insufflation, 265
BOJLÉN, K.: Epidemiological types of dysentery bacilli in Denmark, 443
BONAFÉ, L.: Surgical treatment of intestinal tuberculosis, 14
BONAR, B. E.: Epidemic cerebro-spinal meningitis, 296
Bone, thyroid metastases in, 356
Bone, true, formation of in a cystostomy scar, 514
Bone marrow in anaemia from haemorrhage, 400
BOORSTEIN, S. W.: Fractures of the pelvis, 162
BORCHARDT, W.: Bone marrow in anaemia from haemorrhage, 400
BORGBJAERG, A.: Blood examination in achylia, 273

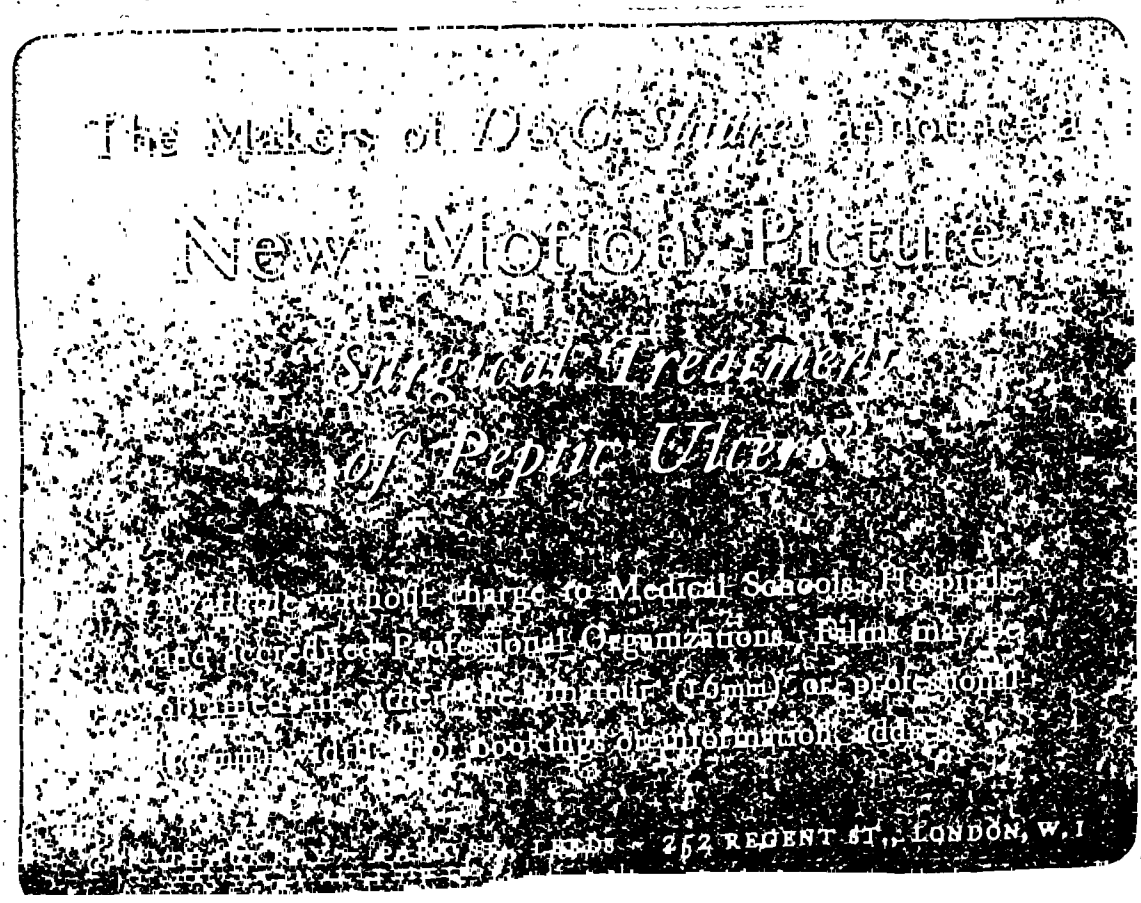
Dependable Gland Products.
2-24, MT. PLEASANT AVENUE, NEWARK, NEW JERSEY.
Export Agents, BROOKS & WARBURTON, LTD., 40-42, Lexington Street, London, W.1.
Specify—CARNRICK. (Trade Mark.)

The Therapeutic value of BRANDY—

its lifting and sustaining powers—as compared with other spirits depends on the presence or absence of the higher Alcohols or Ethers. These in turn depend on Grape, Soil, Stills employed, Climate, Storage, Selection and Experience.

It is quite easy to make a spirit from grape wine—It is neither easy nor cheap to make a Brandy containing the qualities you want.



Cognac Brandy alone provides them.

Take no risks;
ensure the results you expect

Prescribe Brandy distilled in Pot Stills from Wines grown in the best Cognac districts; Matured in warehouses which have been filled with Cognac Brandy for centuries; Made by Men with the inherited Experience of Seven Generations.

In short—Prescribe
MARTELL'S BRANDY

and know that you are doing the best possible for your patients.

British Medical Journal.

It must be understood that the acceptance by the British Medical Association of an Advertisement does not imply a recommendation, and that no responsibility is accepted with regard to the accuracy of the statements therein contained.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

NORRIS and LANDIS' Diseases of the Chest

and the Principles of

Physical Diagnosis

NO revision ever brought to us by its author has been so drastic, so thorough, so complete, so ruthless as this, in the authors' determination to have the new edition reflect absolutely the very newest approved methods in the fields covered.

The new edition of Norris and Landis' "Diseases of the Chest and Physical Diagnosis" had to be reset—because it was virtually rewritten! It would be impossible in an advertisement to give adequate appreciation of the great amount of new material and the painstaking care which this New (4th) Edition exhibits.

Immediately upon opening the book you will realise that you are looking into a mass of new material, a great number of new illustrations, all the new technical tests and the refinements of standard tests.

One of the most important features of this new edition is the new chapter on "The Transmission of Sound Through the Chest," written by Dr. Charles M. Montgomery, who is an unquestioned authority on this subject. In other parts of the book you will find large new divisions devoted to X-ray diagnosis, the relation of nasal accessory sinus disease to infections of the lower air tract, the use of the bronchoscope in diagnosis, latent tuberculosis, tuberculosis in children, many additions and improvements in the chapters on the circulatory system.

In the first section of the book the authors present physical methods of diagnosis, training the reader to interpret signs and symptoms through the eye, the ear, and the sense of touch. The second section of the book takes up the actual diagnosis of diseases of the bronchi, lungs, pleura, diaphragm, pericardium, heart, and aorta. There is also a chapter on the Electrocardiograph, written by E. B. Krumbhaar.

Diseases of the Chest and Physical Diagnosis. By GEORGE W. NORRIS, M.D., Professor of Clinical Medicine at the University of Pennsylvania; and H. R. M. LANDIS, M.D., Sc.D., Director of the Clinical and Sociological Departments of the Henry Phipps Institute, University of Pennsylvania. With a chapter on the *Electrocardiograph in Heart Disease* by EDWARD B. KRUMBHAAR, M.D., Director of Laboratories of the Philadelphia General Hospital. Octavo of 954 pages, with 478 illustrations, some in colour. Cloth, 45s. net.

Just Issued

NOSE, THROAT, AND EAR

By International Authorities

Edited by CHEVALIER JACKSON, M.D., Sc.D., LL.D., F.A.C.S., Professor of Bronchoscopy and Esophagoscopy, University of Pennsylvania and Jefferson Medical College; and GEORGE M. COATES, M.D., A.B., F.A.C.S., Professor of Otology, University of Pennsylvania Graduate School of Medicine. Assisted by CHEVALIER L. JACKSON, A.B., M.D., Assistant in Bronchoscopy and Esophagoscopy, Graduate School of Medicine, University of Pennsylvania. Cloth, 60s. net.

"It would be impossible to appraise the merits of all the articles, so varied and so diverse, but as they must be taken collectively, it may be said that on the whole they maintain a high level and give a faithful picture of the best modern practice, with copious illustrations and admirable coloured plates."—BRITISH MEDICAL JOURNAL.

Published June, 1929

MAYO CLINIC PAPERS OF 1928

Published June, 1929

By WILLIAM J. MAYO, M.D., CHARLES H. MAYO, M.D., and their ASSOCIATES at the Mayo Clinic, Rochester, Minnesota, and the Mayo Foundation, University of Minnesota. Octavo volume of 1,197 pages, with many illustrations. Cloth, 60s. net.

"There could be no better mirror of the progress of surgical science than the Mayo Clinic volumes. Each department of the Clinic keeps itself informed of what is being done elsewhere, and every new suggestion is put to the test on a scale and with a thoroughness which cannot be matched in many clinics."—THE LANCET.

Fourth Edition

HISTORY OF MEDICINE

Recently Issued

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel, Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other pictures. Fourth Edition. Cloth, 58s. net.

"The most readable, and in some respects the most valuable of medical histories. The record of progress is enlivened throughout by touches of human interest. The author is never dull. . . . We congratulate him on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."—BRITISH MEDICAL JOURNAL.

A Mayo Clinic Monograph

CLINICAL ELECTROCARDIOGRAMS

Just Issued

By FREDERICK A. WILLIUS, B.S., M.D., M.S. in Medicine, Section on Cardiology, The Mayo Clinic, Rochester, Minn. Quarto volume of 219 pages, with 368 electrocardiograms. Cloth, 36s. net.

"A large and admirable series of graphic records. . . . The illustrations have been selected with sound judgment and discrimination, they are well reproduced, and to each is appended a detailed legend."—EDINBURGH MEDICAL JOURNAL.

A New Book

PUBLIC HEALTH AND HYGIENE

Recently Issued

By CHARLES F. BOLDUAN, M.D., Director, Bureau of Health Education Department of Health, City of New York. 12mo. of 312 pages, illustrated. Cloth, 12s. 6d. net.

"The writer's aim is to provide a useful introduction, with an adequate historical background, for students of Public Health. His attempt is eminently successful."—EDINBURGH MEDICAL JOURNAL.

Recent Advances in PLANT PHYSIOLOGY

By E. BARTON-WRIGHT, M.Sc., Lecturer in Botany, University of London, King's College. With Foreword by R. RUGGLES GATES, Ph.D., LL.D., Professor of Botany, University of London.

CONTENTS

The Soil and Water Relations of the Plant—Transpiration, the Transpiration Current, Translocation, Root Pressure—Carbon Assimilation—Nitrogen Metabolism—Respiration—Physiology of Growth.

NOW READY.

6th Edition. 21 Plates, 20 in Colour. 348 Text-figures. 18s., postage 9d.

DISEASES OF THE EYE

By SIR JOHN HERBERT PARSONS, *C.B.E.*, D.Sc., F.R.C.S., F.R.S., Ophthalmic Surgeon, University College Hospital; Surgeon, Royal London Ophthalmic Hospital.

"There is no text-book of its size which comprises such a rich and clearly arranged detail in ophthalmology, together with other sciences which bear upon it."
—BRITISH JOURNAL OF OPHTHALMOLOGY.

LONDON: J. & A. CHURCHILL, 40, Gloucester Place, Portman Square, W.1.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

NEW YEAR RESOLUTIONS.

We have endeavoured for the past 22 years to preserve, unbroken, our resolve to give our members efficient service.

YOUR SUPPORT HAS ENABLED US TO—

Build up a Premium Income of **£100,000** a year;
Save you, by way of Rebates on Premiums, **£37,000**;
Contribute to Medical Charities **£23,000**;
Make Grants for the Education of several sons and daughters of deceased or disabled Medical men and women;
Arrange Loans for Purchase of Practices.

OUR RESOLVE FOR 1930—

Is to continue and, if possible, increase our activities on your behalf.

MAY WE SUGGEST YOUR RESOLVE FOR 1930—

Be to afford us even greater support and thus enable us further to benefit yourself and those deserving causes we are privileged to assist.

We shall be pleased to deal promptly with your enquiries for:—

LIFE, ENDOWMENT, and CHILDREN'S ASSURANCES, ANNUITIES, MOTOR CAR, HOUSEHOLD, FIRE and BURGLARY INSURANCES, Etc.

An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

AN INTERESTING LEAFLET giving diagrams and instructions, post free on request. Please ask for a copy.

What do X-rays mean to you?

DO you instinctively think of a room full of mysterious apparatus, crackling sparks and costly equipment? Do you think of years of scientific training, that terrible affliction X-ray dermatitis and the dangers of possible electrocution? Do you think of complicated switchboards, delicate glassware and the weirdness of the effect generally on a nervous patient? Abreast of the times you do not. The dangers have vanished. The difficulties have all been eliminated. That is progress.

Do you ever query why every Hospital now possesses its own X-ray installation? Knowing its importance to the community, you do not. That is merit. To the importance of X-rays in private practice you can also testify.

You will remember your own problem—the numberless instances when, in the interests of your patient and in fairness to yourself, you have felt that a first-class radiograph would have made your diagnosis certain. That is necessity.

The need you have so often felt for something simple, something you could work yourself. In brief, an outfit which, being inexpensive, requires no technical knowledge, can be operated without the slightest element of risk, taken if necessary to the patient's house, and above all will turn out work of the highest quality.

In such a category comes the "METALIX-PORTABLE." We invite you to write for particulars.

PHILIPS LAMPS LTD. (X-RAY DEPT.), PHILIPS HOUSE, 145, CHARING CROSS ROAD, LONDON, W.C.2

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

This preparation is now obtainable in 5-oz. bottles.

MIST. DAMIANÆ CO. (HEWLETT'S).

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally.

In all the various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose: One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles. Price in England 12/6 per pound.

Introduced and Prepared only by

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte St., London, E.C.2.

INFLUENZAL "COLDS"

Alkaline therapy in some form has given the best results in all the recent epidemics of influenza and colds. The particular form of alkaline therapy represented by the administration of SALVITAE has always, when given a fair trial, proved to be the most dependable resource of all.

The Antiseptic of Proven Worth

The last decade has witnessed such a notable increase in the number of antiseptics of varying degrees of efficiency that it has become important for the physician and the surgeon to discriminate between the preparation of proven worth and that of unknown value.

The germicidal power of Acriflavine 'B.D.' Brand has been proved by clinical experience covering a period of thirteen years. Acriflavine 'B.D.' Brand is a product of wide application, and the fact that its potency is increased in the presence of serum gives it a distinct advantage.

It is particularly valuable in the treatment of wounds, gonorrhœa, lymphangitis and tonsillitis.

Acriflavine 'B.D.' Brand is issued in powder form, also in tablets, in solution, in an ointment, in bougies and suppositories.

CASEIN-SODIUM-GLYCEROPHOSPHATE

Samples and literature will gladly be sent on application to

GENATOSAN LTD., LOUGHBOROUGH, LEICESTERSHIRE.

In Chronic Indigestion Bemax "showed very satisfactory results."

Dg. 59.—Bemax was prescribed to several patients for "Various chronic digestive ailments, with very satisfactory results."
——, M.D.

Dg. 38.—In a case of general debility, chronic gastritis, and lack of assimilative power. "Half way through the tin definite benefit. She wishes to continue Bemax." ——, M.B.

Dg. 2.—My wife began to notice improvement after five weeks. Since then she has put on seven pounds in weight and lost her indigestion. She is much better generally. ——, M.D.

Perhaps the most serious result of a vitamin deficient diet is the resulting degeneration of the intestinal muscular and nervous tissues.

Not only does the body become progressively less capable of absorbing nourishment from the food consumed, but the muscular coats, areolar tissues and mucous membranes degenerate, and the peristaltic wave is thus enfeebled.

By restoring a healthy metabolism, Bemax recreates a condition in which healthy digestion is possible and at length inevitable.

The excellent results obtained through its use by medical men in cases of Indigestion, Intestinal Toxæmia, Chronic Constipation, Debility, Neurasthenia, and Rheumatism afford ample evidence of its therapeutic value in all "deficiency diseases."

Bemax is a natural food prepared from the living embryo of cereals. It has a higher content of natural Vitamin B than any other known substance.

Laboratory reports on Bemax and a free tin for trial will be sent to any medical man on receipt of his professional card.

BEMAX

The Most Concentrated Extract of Natural Vitamin B.

THE BEMAX LABORATORIES, 38, DANEMERE STREET, LONDON, S.W.15.

VITAD PALATINOIDS

¶ VITAD is the unsaponifiable fraction of Cod-Liver Oil containing in a high concentration Vitamins A and D.

¶ While presenting practically the full medicinal properties of Cod-Liver Oil, it is free from the nauseating oily fraction. Being exhibited as a Palatinoid, it is protected by the hermetically sealed non-actinic covering from all chance of oxidation and light action, thus ensuring a standard dose at all times.

¶ Palatinoid Vitad is put up in bottles of 25 and 100, and in two strengths:

m. 1½ for Children
m. 3 for Adults.

Two palatinoids respectively represent the full daily dose of Vitamins A and D.

a new antiseptic

QUINANIL

ANIL - QUINOLINE 48 S

THIS important new antiseptic is the result of Research carried out by a group of workers at the University of Leeds under the auspices of the Medical Research Council. It has been subjected to thorough clinical trials in the General Infirmary, Leeds.

Boots Pure Drug Co. Ltd. have been supplying QUINANIL for these clinical trials, and the results were reported in the LANCET of November 9th, 1929.

Every batch of QUINANIL-BOOTS is submitted to the University of Leeds for approval before issue, and ample supplies are now available for the use of the Medical Profession.

QUINANIL is usually employed in solution in normal saline. The strengths used have varied from 0.005% (1:20,000) to 0.1% (1:1,000). See LANCET of November 9th, 1929, p. 969.

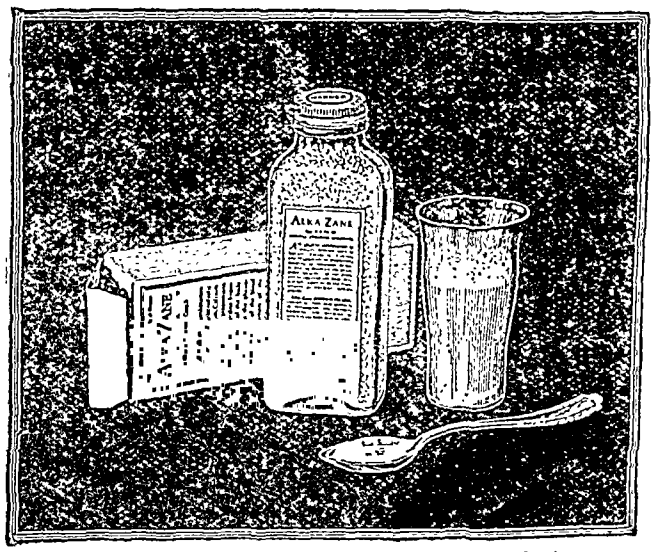
IT IS PLEASANTER TO USE

K-Y Jelly is greaseless and does not soil the clothing or irritate the skin. It flows freely, never binds, and can be squeezed out of its tube quickly and conveniently in exactly the quantity required. It is easily removed from hands and instruments by rinsing them in water. Prepared from vegetable substances blended with correctly balanced proportions of boric acid, K-Y Jelly is more "slippery" than petrolatum and never spoils or becomes rancid or poisonous. Physicians and surgeons are invited to write for samples to Dept. B, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating name of their local supply house.



* * *

Lubricating Jelly is obtainable from supply houses and pharmacists all the world. Tubes in cartons, 1/3 [illegible] size, 2/6).

K-Y JELLY FOR INTERNAL EXAMINATION

JOHNSON & JOHNSON (GT. BRITAIN) LIMITED, SLOUGH AND LONDON

ALKA-ZANE

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

is a palatable and rational antacid, indicated in all conditions of relative hyperacidity, rheumatism, gout, intestinal, gastric, and certain cutaneous disorders.

Prompt in action, lasting in effect, it promotes diuresis, neutralizes excess acid production and helps to rebuild the alkaline bases.

The efficiency of Alka-Zane is demonstrable by the briefest of trials.

A New Stride Forward in Nose and Throat Therapy

Mistol is a combination of eucalyptol, menthol and camphor in a specially prepared base of petrolatum. It is approved by leading nose and throat specialists for its quick action in relieving irritated and infected mucous membranes.

Due to its oily consistency, Mistol clings tenaciously to mucous membranes, keeping its soothing and astringent ingredients in direct contact with the inflamed parts for a considerable length of time.

Mistol

Made by Nujol Laboratories.
128, Albert Street, Camden Town, London, N.W.1.

Over Half a Century of Clinical Experience has established its reputation as

"THE STANDARD TONIC"

Samples and Literature upon request

FELLOWS MEDICAL MANUFACTURING CO., Inc.
26 Christopher Street, New York, U. S. A.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & CO. LTD.

BOOTS PRODUCTS

"VITAMALT" Regd.

RICH IN ESSENTIAL VITAMINS A, B, C & D.

Clinically tested at regular intervals, it has been demonstrated that Vitamalt is an extra-dietary food of considerable value.

Containing Vitamins A,B,C,D in the proportion now recognised as suitable for most requirements, Vitamalt affords the treatment necessary to counteract the conditions arising out of lack of these important factors. Infective processes are controlled by its content of Vitamin A, while the proportions of Vitamins B and D are such that the tonic action is greatly enhanced.

Vitamalt is of considerable importance to children who suffer from malnutrition and is a valuable adjunct in their treatment.

SAVORY & MOORE'S FOOD

FOR INFANTS OR DELICATE ADULTS

The value of Savory & Moore's Food has for many years been recognized by the Medical Profession. The consistent success, met in such extreme cases as the premature Infant whose life is despaired of, to the elderly patient suffering from digestive disorders or insomnia, enables the Food to retain its prominent position in the Medical mind.

"I have tried your Food in case of chronic dyspepsia in an elderly patient suffering at the time from a chill. The Food was well taken and retained when various other foods did not agree." ——, M.D.

"Your Food is easily digested and ideal for patients with gastric trouble and those recuperating from abdominal operations. It has a pleasant flavour and is different from the everyday foods." ——, Supt., Nursing Home.

Prepared as directed Savory & Moore's Food contains the Vitamins and Enzymes which are essential for healthy growth and development in Infants or the sustenance of enfeebled Adult Digestion.

SAVORY & MOORE'S FOOD
may be prescribed with confidence.

Samples for trial will be forwarded free to Members of the Profession if desired.

"I consider your Infants' Food very good. Two of my own children have done very well on it. I have found children do well on your Food after several other makes have been tried without result." ——, L.R.C.P., M.R.C.S.

"For many years I have ordered Savory & Moore's Food with excellent results. In my experience about 95 per cent. of children are able to digest and assimilate your product." ——, M.B., Ch.B.

BY APPOINTMENT

ORIGINATED NEARLY A CENTURY AGO . . . THE MEDICAL PROFESSION HAS ADOPTED THEM EVER SINCE

BRAND'S Essences were first made by Mr. Brand and a amous doctor in 1832. Since that time, they have been the standby of the Medical profession.

Rich in phosphates and the stimulating properties of meat, Brand's Essences are invaluable for al states of exhaustion and during convalescence When patients are listless and reluctant to eat, a diet of Brand's Essence will bring back the appetite and induce them to take more solid food.

Brand's Meat Essences have a stimulating action on the gastric juices and can be rapidly absorbed without strains on the d'gestive organs.

They are the pure uices of meats extracted by an exclusive method and sterilized by heat processes under scientific supervision.

Brand's Essences (Beef, Mutton and Chicken) can be obtained at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

BRAND'S ESSENCES

(BEEF & CHICKEN)

DIGESTIBILITY

is an outstanding advantage secured by specifying

'WHITE BEAR' BRAND

Cod Liver Oil

TRADE MARK.

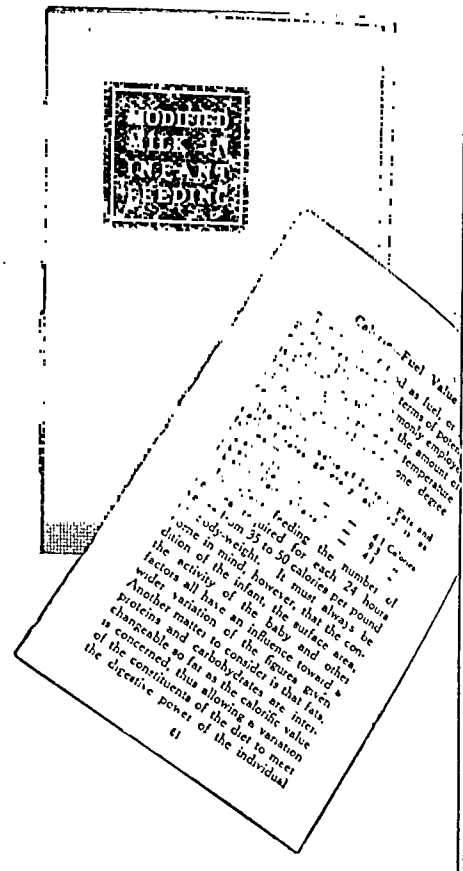
A first-grade Norwegian oil of unquestionable purity. Prepared by the latest scientific process designed to exclude the impurities of decomposition and oxidation. It is exceptionally free from taste and odour, whilst the Vitamin content and the physiological activity of the oil are fully preserved. Patients take White Bear Brand Cod Liver Oil readily and digest it with the minimum of effort. The price, too, is advantageous.

Supplied in 4 oz., 8 oz., 12 oz., 16 oz., and 20 oz. bottles by all Chemists

HIRST, BROOKE & HIRST, LTD., LEEDS.

London Distributors: JOHN BELL & CROYDEN, 50-52, Wigmore Street, W.1.

BOTTLE-FED BABIES.



The difficulties that attend hand-rearing are minimised by the use of cow's milk modified by

Mellin's Food

The physical texture of the casein is thereby modified, the carbohydrate constituent raised, and the saline ingredients adjusted, so that the resulting mixture gives most satisfactory results under all average conditions.

Samples and directions for feeding, as well as suggestions for the modification of milk by means of Mellin's Food in cases of malnutrition, diarrhœa, or constipation, will be gladly forwarded by:

MELLIN'S FOOD Ltd., LONDON, S.E.15

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD

Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

A useful adjunct in the Treatment of RHEUMATIC AFFECTIONS

Reports received from Practitioners indicate that many cases of Rheumatic Affections have been successfully treated with Detoxicated Anti-Rheumatic Vaccine (*Genatosan*).

This vaccine now contains seven varieties of streptococci, including three new strains of osteotropic streptococci recently incriminated in the causation of rheumatism. Detoxicated Anti-Rheumatic Vaccine is an agent of great value in the treatment of acute and chronic rheumatism and rheumatoid arthritis.

A summary of recent discoveries regarding the bacteriology of Rheumatism appears in the Genatosan "Twelfth Vaccine Bulletin and Supplement." These booklets have been despatched recently to all Practitioners whose names appear in the Medical Register, and any Doctor who has not received them owing to change of address or other reasons is invited to write for copies which will gladly be sent free by the Vaccine Department of

BACTERIOLOGY of MILK

Bacteriological sterility is perhaps one of the most important desiderata in the feeding of Infants. Periodical outbreaks of milk-borne epidemics are evidence enough that raw liquid milk is still outside the pale of safety; and the continual presence of tubercle bacilli in milk renders some form of treatment essential.

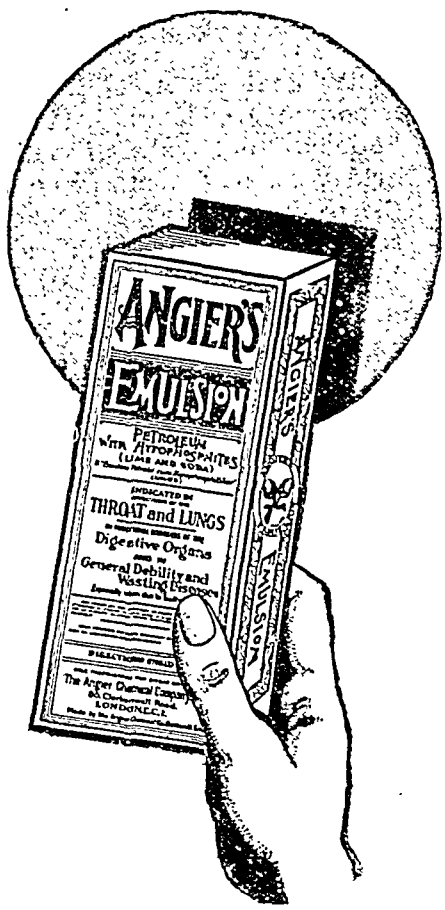
Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

The accompanying micro-photographs illustrate the comparative degree of purity of different grades of milk and are convincing proof of the reliability of Cow & Gate Milk as opposed to all other forms of milk.

The bacteriological purity of Cow & Gate is assured by an Improved Roller Process which, unlike other forms of heat treatment, involves a minimum exposure to heat, and preserves intact the natural and rich vitamin content of the original West Country milk.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.



COW & GATE Ltd.,

GUILDFORD.

For Children

in Bronchitis, Whooping-Cough, Measles, and Scarlet Fever.

Angier's Emulsion is one of the most useful and dependable remedies at the command of the physician for the treatment of the various inflammatory and bacterial affections of children. Its soothing, inflammation-allaying properties and its general tonic effects are of first importance in these ailments, while its pleasant cream-like flavour and ready miscibility with milk make it easy of administration even to the youngest infants

In many of the wasting diseases of childhood a sensitive, irritable stomach and intestines preclude proper nourishment. Under the administration of Angier's Emulsion these organs become pacified and retentive, digestion is strengthened, and the assimilation of food is normal and complete. We confidently urge its trial in marasmus, scrofulosis, inherited tuberculosis, anæmia, and in the malnutrition associated with acute infectious disease.

MAP SHOWING EARLIEST PIONEER WORK OF THE ARABS.—An advanced stage of civilisation was reached in this region and the way paved for the builders of the great Mohammedan Empire. The forward march of the Arabs began long before the spectacular advent of Mahomet and the Saracens. The earlier advance may account for the apparent suddenness of the later achievement. The Sabæans, in the region now known as Yemen, were probably the earliest pioneers of Arab civilisation. They penetrated to other regions where they represented the superior caste and played an important part in the rise of new states, as for instance, that of the Lakmids on the Euphrates. To the kings of Saba succeeded, perhaps in 115 B.C., the Himyarite or Homerite dynasty, who held the title "Kings of Saba and Raidan" down to A.D. 300, after which they became Kings of Saba, Raidan, Hadramaut and Yemen, retaining this title till the break-up of their power in the sixth century A.D. Streams of migrants spread the civilisation they had achieved, and notable among these were the founders of the Aksumite kingdom in N. Abyssinia, where they built temples, palaces, dams and reservoirs, beginning during the last centuries of our era.

THE "LAND OF THE SABÆANS," THE MOST RENOWNED OF THE KINGDOMS BUILT UP BY THE ANCIENT ARABIANS.—The earliest mention of the Arabs of Yemen occurs in the Hebrew scriptures: their kingdom was known as Sheba or Saba. The Sabæans were caravan traders in incense and perfumes, gold and precious stones, ivory, ebony and costly garments. Remains of Sabæan cities and colonies provide widespread evidence of commercial enterprises and caravan routes. We easily realise that the Queen of Sheba's (Saba) visit to Solomon would present no problem to the practised travellers of S.W. Arabia. The vast quantities of incense required for the religious rites of all the countries of the then civilised world made the incense country, *i.e.*, the Land of Saba and the Land of Punt, on the shore of Africa opposite, an incomparably busy centre of export trade. Pliny relates that the gum was collected from the incense trees of Yemen by the men of 3000 families who alone had this right. The incense was taken to Shabwat in Hadramaut, where a tithe was withdrawn by the priests.

The accompanying illustration shows the branch of the incense tree, which was the chief source of the prosperity of Sheba.

★ CHILBLAINS

★ *Colloidal Calcium with Ostelin vitamin D*

"I used the latter *(Colloidal Calcium with 'Ostelin' Vitamin D Ampoules)* at once in treatment of acute chilblains, with immediate improvement. 3 injections alternate days cleared up the condition and the injections will now be given weekly."

——, M.B., Ch.B., 21.11.29

The introduction of Colloidal Calcium with "Ostelin" Vitamin D Ampoules for hypodermic injection places at the disposal of the practitioner a method of treatment, the value and applicability of which will at once be apparent in a large and varied class of cases.

The presence of the Vitamin D in addition to the Calcium besides giving a very pronounced tonic effect, rationalises the administration of Calcium and further prolongs the effect, as it facilitates the absorption and utilisation of Calcium from the bowel.

Clinical Indication.—In vaso-motor skin affections, *chilblains*, chilblain circulation, urticaria, in gross nutritional failure occurring in debility diseases, and also in delayed union of fracture, these Ampoules have proved of value.

Literature and Free Supplies for clinical trial will gladly be sent on request.

Price Five Shillings per box of Six Ampoules subject to usual professional discount.

An Address
ON
SOME CLINICAL ASPECTS OF PAIN.*

BY

EDWIN BRAMWELL, M.D., F.R.C.P.,

MONCRIEFF-ARNOTT PROFESSOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH.

PAIN is the commonest symptom of disease; there is no symptom more informative to the practitioner and none at times more misleading; again, there is no symptom more distressing to the patient and none that so often gives rise to mental misconceptions.

The subject of pain bristles with attractive problems, to some of which only is it possible to refer. A rambling discourse, with reference to illustrative cases, would appear to be more suitable for present purposes than a systematic disquisition. If, then, certain aspects of pain are dealt with in what may appear to be a sketchy and haphazard manner, no apology is called for, since it will be thereby possible to cover a wider field.

What do we mean by pain? While the word is sometimes used to express a state of mental anguish or distress, it is commonly applied to a recognized type of bodily discomfort. It is to pain in this sense that these remarks refer. Here again, however, it is to be remembered that one individual will describe as pain a sensation to which another would not apply the term. Pain is indeed difficult to define, but since we all know what we mean when we speak of pain, in the common acceptance of the word, a definition would appear to be unnecessary.

Does pain fulfil any useful purpose—is it, in other words, of any economic value? If not, why should the human race be cursed by a symptom which is the cause of so much suffering? The pains of labour afford an instance, perhaps the only instance, in which pain is the constant accompaniment of a physiological process. But since the pains of labour are related to the evolution of civilization—for they are, I understand, comparatively trivial in the primitive races of mankind—they may perhaps be regarded as pathological. Sir Charles Sherrington has referred to pain as "a psychical adjunct to a protective reflex." Pain is indeed a protective danger signal, and, since it affords a warning that all is not well, it fulfils an invaluable purpose. In so far as pain is informative it must be regarded as an indispensable blessing, while it is, at the same time, one of the curses to which the human flesh is heir.

All the information regarding subjective pain that we possess has been acquired from personal experience or from the statements and reactions of the sufferer. On the other hand, our knowledge of objective pain and its subservient mechanism has been largely derived from a study of (1) the effects which result from localized disease of, and more particularly injury to, the peripheral nerves, spinal cord, and brain; (2) the phenomena which follow experimental nerve division in man; and (3) the "referred pains" and areas of cutaneous hyperalgesia which are met with in disease of the various viscera. Animal experiment has afforded us but little help in this connexion. Do the lower animals feel pain, and, if so, to what extent? This is a question which is difficult to answer. Professor Edinger of Frankfurt, one of the greatest comparative anatomists of his day, was of opinion that the lower forms of vertebrates, in which the pallium is wanting, do not feel pain. On the other hand, we now know that in man the thalamus is the centre in which crude sensations of pain are experienced. The reflex withdrawal of a limb which follows the application of a stimulus is no proof that the animal suffers pain. This is an independent phenomenon, as is demonstrated by the fact that in certain cases in man, in which conduction in the spinal cord has been interfered with by disease or injury, the lower limb is drawn up reflexly when the skin is pinched, although there is no accompanying painful sensation. Sir Edward Sharpey-Schafer writes: "Nothing is more certain than that pain is not a primitive sensation; it is in fact the latest sensation to be evolved." There appears, indeed, to be no doubt that the appreciation of pain is more acute the higher we ascend the evolutionary scale.

Individuals differ greatly in their sensitiveness to, and tolerance of, pain. Some are hypersensitive, others hyposensitive. Again, the threshhold for pain in the same individual differs in different situations, and varies from time to time and under different circumstances. Further, while one individual tends to minimize, another tends to exaggerate. This tendency, which applies to all subjective symptoms, may be "temperamental," while, on the other hand, it may be determined or influenced by extraneous circumstances. Unfortunately we possess no instruments of precision or other means whereby the clinician can measure pain and record comparisons in scientific terms. A conclusion can only be arrived at in terms of a general impression after a judicial consideration of all the circumstances. The appreciation of the subjective constitutes a large part of the art of medicine.

Anatomical and physiological considerations regarding the path of the nerve fibres which conduct painful impulses need not detain us. Suffice it to say that there are special afferent fibres which pass by way of the peripheral nerves to the spinal cord and brain stem. Soon after entering the central nervous system the path for pain decussates and terminates in the optic thalamus. Here the nerve impulses are appreciated in terms of pain and are recognized as diffuse, unlocalizable, disagreeable sensations. The function of the cerebral cortex, which is directly connected with the thalamus by fibres arising in the latter, is to localize these sensations and analyse their significance.

Pain is usually due to excitation of peripheral nerve terminals, but it may be directly determined by stimulation of the peripheral nerves, while it is very exceptionally a consequence of disease which involves the conducting tracts in the spinal cord and brain stem or the thalamus itself. Most of us have probably met with cases of epidemic encephalitis in which intense pain has been a striking symptom. The thalamus is often implicated in this disease, and the pains which result may present similar features to those met with in the thalamic syndrome of Dejerine.

The manner in which pain may be produced, as a consequence of excitation of the peripheral nerve terminals, calls for passing notice. Noxious stimuli of various kinds may, as we are well aware, excite the nerve endings in the skin and give rise to pain; again, we have all experienced the pain which accompanies muscular cramp, and we have observed the hyperalgesia of the muscles in alcoholic neuritis and the analgesic muscles in some cases of tabes; further, we are familiar with the joint pains in an acute arthritis, and with the excruciating pain in cases

* Delivered to the North Northumberland Division of the British Medical Association on November 12th, 1929. The subject of pain was treated on somewhat similar lines in a British Medical Association lecture (unpublished) delivered by the author to the Dumfries and Galloway Division of the Association on February 21st, 1928.

in which malignant tumours involve the bones. But the problem of pain in relation to visceral disease is somewhat different. When such organs as the lungs, the liver, or the spleen are affected by disease, pain is not complained of unless the investing serous membrane is implicated. Then, again, ulceration of a hollow viscus may exist for years without producing the slightest distress. "It is, indeed, a basal fact of clinical observation," as D. P. D. Wilkie writes, "that most abdominal pains, if we exclude those of the parietal peritoneum, are due either to spasm of, or tension in, the hollow viscera." The pain in such circumstances, as exemplified by the various types of colic (gastric, intestinal, biliary, renal, etc.), is either a direct consequence of the spasmodic contraction of the muscular tube in its attempts to force its contents beyond an impediment, or of a passive distension of the tube above the site of obstruction. Then, too, it is an interesting fact that pains arising in the internal organs are very inaccurately located and are misreferred, as reflected or referred pains, to more or less definite areas of skin on the surface of the body corresponding to the spinal segments from which the organs in question are innervated. There is, too, another well-recognized causal factor in the production of pain. I refer to interference with the blood supply, as exemplified by Raynaud's disease, intermittent claudication, and some cases of angina pectoris associated with disease of the coronary arteries. How difficult it is to appreciate the characters of a sensation one has not personally experienced; how difficult even for the trained observer to describe his sensations, how difficult to gauge the intensity of pain in the individual case!

A physician of wide experience once asked me to examine him, since for three days he had been troubled with what he described as a severe pain, which he referred to the side of the chest. Upon examination I found no objective signs, and ventured to predict that the pain might be the precursor of an attack of herpes zoster. "I have seen many cases of herpes zoster," said the patient, "and I am sure that this is not the pain of shingles." Nevertheless, on the following day the herpetic rash made its appearance.

The practitioner is called upon to regard the symptom pain from three points of view: first, as a phenomenon which often affords important information in diagnosis; secondly, as a symptom which may in itself call for treatment because of the distress or disability it produces; and, thirdly, as a possible source of misconception on the part of the patient; this, if uncorrected, sometimes determines a state of apprehension and anxiety, which may culminate in prolonged or permanent invalidism.

Pain is responsible for many diagnostic difficulties and pitfalls. All of us have met with cases in which a referred pain from a basal pleurisy has closely simulated appendicitis, with pain referred to the left breast by women suffering from pelvic disease, and with epigastric pain due to disease of the dorsal vertebrae. Again, we have met with cases in which the pains of tabes dorsalis have simulated disease of the stomach and other organs, and cases of hysteria in which acute visceral disease has been so closely imitated that the surgeon has been induced to open the abdomen. Many other instances of the kind might be cited. But it is not my present purpose to discuss the significance of pain as an indication of organic disease, the misleading features it may present, and the many niceties in diagnosis which occur in this connexion. Nor is it my intention to refer further to the treatment of pain attributable to, and adequately accounted for by, obvious physical causes. I would now consider another aspect of pain which calls for consideration, the more so since it does not perhaps receive the diagnostic attention which its importance merits.

Whereas pain is commonly attributable to physical causes and may consequently be termed physiogenic, since it is directly referable to a recognized physiological mechanism, it may, on the other hand, be of mental origin, or at least modified by the attitude of the mind. To this type of, or factor in, pain the term "psychogenic" is applicable. Reluctant as one is to adopt a nomenclature which is not in common usage, this becomes imperative if the terminology expresses an idea which serves to clarify existing conceptions. The terms "physiogenic" and "psychogenic" are peculiarly applicable to the symptom pain, for, as R. D. Gillespie points out, "the differentiation of physiogenic from psychogenic is not precisely the same as the differentiation of 'organic' *from 'functional,'* for 'functional' can be physiogenic." A correct appreciation of the etiology of pain in any given case is a necessary preliminary to rational treatment, hence the necessity for a precise etiological terminology. My remarks have so far been devoted to a brief consideration of physiogenic pain; let us now consider some aspects of its psychogenic counterpart.

The attitude of individuals towards pain is very different. I have by me a pamphlet written by a layman nearly two hundred years ago, evidently an irresponsible, happy-go-lucky fellow with a keen sense of *humour*; would that we could all share his cheery optimistic attitude as he writes upon the "Honour of the Gout"! Listen to what he says:

"Get me two men together, one that never knew Pain, and another newly recovered of the *Gout*; observe them both narrowly. In the former, perhaps, you may perceive an easy, even Temper, but the latter is ravished with Joys and Satisfactions, which if his tongue does not declare, his Hands, and Feet and Gesture shall. . . . Such are the lucid intervals between Heart-breaking Fits of the *Gout*, with all its Ravings and Roarings which the violent Paroxysm forces from the tortured Patient; and who would spoil the refined Pleasure of his Recovery, by wishing to have one angry Throb, one heavy groan bated him? . . . O, so pleased, so joyous, so happy, so blessed will you be, when the Turn of Health shall come. Why, Sir, you will be in Heaven, in Heaven while you are on Earth."

We do not like to be advised to curtail our interests and forgo our pleasures; we may, indeed, resent advice to this effect.

A lawyer, a man of ability, consulted me some years ago, not because of pain it is true, but on account of sleeplessness—a symptom which he said had troubled him for many years. As a result of my inquiries I ascertained that the patient was a very heavy smoker, that he had once given up smoking for six weeks, and that during this period he had slept well. The result of a prolonged examination was otherwise negative. The therapeutic indications appeared obvious, but when it was explained to the patient that the evidence was most suggestive to the effect that tobacco was the cause of his insomnia, and that he should at least cut down his smoking, his reply was, "I did not come to you to be told that, doctor, but to get something for my sleeplessness."

A forcible expression of opinion is sometimes necessary if it is to be effective.

A society woman, accustomed to enjoy to the full the pleasures of life, complained of a precordial pain which was interfering with her activities. She was seen by a heart specialist of world-wide reputation. A few questions and a brief examination served to elicit the essential facts. The diagnosis presented no difficulty, the indications for treatment were obvious, and after a short talk the physicians returned to the patient's room. "My lady," said the specialist to the spoiled child of fortune, "you are suffering from a pain which you are right in supposing is due to your heart. I might give you something which would relieve the pain, but I don't propose to do so. The pain is a warning to you to curtail your activities and live a different life." With this remark he turned and left the room. The advice was perhaps not unexpected, but the manner in which the opinion was expressed was so unlike that which the patient had been accustomed to receive from the physicians whom she had previously consulted that it came as a thunderbolt. Whether it achieved its purpose history does not relate.

Such is human nature! After all, we can only put the facts before our patients; it is for them to decide whether they will follow our advice. The doctor can only advise, he cannot coerce.

The influence of the attention upon pain is familiar to us all. We know that when we concentrate our attention upon a pain the pain is intensified, while, conversely, when our attention is distracted or otherwise occupied, the pain is much less apparent. The mother of the teething child tries to engage the child's attention, and when she is successful the pain is for the time being forgotten. This fact, which is constantly applicable to the subjective symptoms of disease, is of great therapeutic importance, especially in those cases in which the fixation of the attention upon the symptom in question is determined by anxiety as to its significance.

This observation raises the question whether, or to what extent, pain may persist as an after-memory, the conse-

quence of a stimulus that now no longer exists. Although unusual, this undoubtedly occurs. Fortunately our memory of pain is usually short-lived. I cannot, for instance, recall the case of a woman who has continued to be distressed by the memory of her labour pains after her child was born. The explanation may be that the pains, intense though they were at the time, are of short duration. On the other hand, it may be that the mother's thoughts are so concentrated upon the newborn infant, or on other matters, that her attention is distracted from her previous suffering. Again, it may be that she knows that the cause of the pain is now non-existent. An illustration of the fact that a pain may persist as a memory in the brain, after the peripheral stimulus which was originally responsible for its determination has ceased to act, is afforded by the following case.

A miner was admitted under my care suffering from sciatic pain, which he informed us had been continuously present and had incapacitated him for two years. The ankle-jerk was absent in the affected leg, an indication that he had almost certainly had a sciatic neuritis. On the other hand, there was no tenderness on pressure over the sciatic nerve or its branches. The patient appeared to be a good fellow, he was receiving no compensation, and he told us he was very anxious to be cured and to get back to work. After considering the facts we came to the conclusion that the pain was an after-memory. He was told of the conclusion we had come to and our reasons explained to him. The pain disappeared in a few days, the patient returned to work, and continued to work steadily from that time on.

A diagnosis in a case of this kind is often very difficult, notably when evidence of structural changes coexists which would appear to be sufficient to account for the pain; while, further, a confident diagnosis is essential if a cure is to be effected.

Some individuals are able to experience pain by an effort of the imagination—*pain which is as intense as a pain due to peripheral stimulation.* Thus a friend of mine, a very able member of our profession, tells me that he can imagine himself sliding down a sloping roof until his heels come into violent contact with the balustrade below. He says that he can feel the pain in his heels and the jar to his spine as vividly as if the accident had actually occurred.

Now if pain can be voluntarily induced, and if it may persist as an after-memory, it is not difficult to realize that it may originate in an idea. There can, indeed, be no question that some of the neuralgias, neuritic pains, rheumatic pains, and headaches with which we meet in practice are so determined or maintained. Again, we must remember that psychogenic pain is very real pain, and consequently, in speaking to the patient, it is inadvisable to use the words "hysterical" or "imaginary," for, unless we explain exactly what we mean, these expressions are apt to be misunderstood, and our supposed attitude may be resented by the patient. The following case of psychogenic pain is so instructive that I am tempted to describe it in some detail.

The patient, a man in the early twenties, a cripple since childhood, whose every want had been attended to by a devoted mother and sister, was admitted to a nursing home. A history was obtained from the patient's medical man to the effect that he had been called to see the patient some eight weeks previously, when he found him suffering from a severe pain over the left side of the chest, near the costal margin, for which, upon examination, he could find no cause. The pain continued to recur at the same time—ten minutes to ten each night. It was very severe, and drugs failed to relieve it. Every night for the six preceding weeks the doctor had had to keep the patient under the influence of chloroform for nearly two hours; the pain then passed off until the following evening at the same hour. When seen, on the afternoon of his admission to the nursing home, the patient stated that he felt perfectly well, excepting at those times when he was suffering from pain.

Upon examination no objective signs were detected to account for the pain. The conclusion was come to that the pain was psychogenic in view of its periodicity, the fact that the patient appeared to be unduly suggestible, the obvious concern shown by his relatives in his presence, and the absence of any other adequate explanation to account for the facts. The diagnosis was incomplete in that we failed to elicit the determining mental factor which had been responsible for the localization of the pain, a point of the greatest value in establishing, or corroborating, the diagnosis in cases of the kind. A line of action was determined upon, and the physicians returned that evening shortly before the hour when the pain was to be expected.

The picture was one never to be forgotten. The room was dimly lighted, the patient was breathing heavily and was apparently asleep. His mother, his sister, and two nurses were in attendance. As the physicians entered the room the mother approached them with her finger to her lips, and whispered, "It is not quite time," and they sat down to wait in an expectancy of silence. Precisely at ten minutes to ten the patient moved in his sleep, and began to give vent to groans, which gradually increased in intensity as he rolled from side to side in apparent agony. In accordance with a preconcerted plan the patient was asked to inhale some amyl nitrite, with the remark, "This will help you." When asked after a minute or two whether the pain was improving, the patient's answer was "Not yet." This response was in itself encouraging. A few minutes later the patient admitted that the pain was abating, and before long he said that it had gone. Then he was told, "You will have no more pain," and the physicians left the room. The patient's mother and sister followed. "It is wonderful," they said; "will you come to-morrow night and give him some more treatment?" The reply was, "No; there will be no recurrence of the pain, but we want you to leave the patient to the care of the nurses and not visit him again until we give you permission." The prediction was correct; the pain did not return.

This case serves to impress many lessons. Thus, among other things, it demonstrates that severe pain may occur in the absence of an organic or other accountable physical cause; that precise and inexplicable periodicity should suggest the possibility, although it does not necessarily imply, that the pain is of mental origin; that a diagnosis of psychogenic pain is based partly on the exclusion of an adequate physical cause and partly upon an estimation of the individual's suggestibility, together with a consideration of his attitude to his surroundings and the detection of a determining factor to account for the localization of the pain; that a psychogenic pain may be fostered by undue attention; that a pain of the kind may be cured by suggestion or persuasion; and that, in successfully dealing with such a pain, confidence in diagnosis and a confident expression of opinion are essential.

The psychogenic factor in pain is often determined and often maintained by suggestion. How foolish people are! They are constantly making remarks to their friends who have been or are ill. "How are you?" "You are not looking up to the mark." "You look as if you require a holiday." "I hope your pain is easier," and so on. Such remarks draw the patient's attention to his condition, the very thing we are so anxious to avoid. The individual in whom the psychogenic factor is prominent is for the time being a suggestible individual.

A psychogenic pain may be suggested by a previous illness.

A man who had suffered in early childhood from tuberculous disease of the spine fell and struck his back. From that moment he complained of pain in this situation. When examined some weeks later there was evidence of old tuberculous disease of the spine, but no indications of fresh injury. The patient had not apparently fallen very forcibly, yet he complained of severe pain in the region of the old disease. After a careful consideration of the facts the conclusion was come to that the pain was psychogenic. A confident opinion was given to the effect that the pain was not due to a recrudescence of the disease, the patient's anxiety was relieved, he was encouraged to move and walk about, and in two or three days the pain had disappeared.

Again, pain may be suggested by the surroundings in which it had originally appeared.

A woman had an extremely painful whitlow, which was opened, and was followed by nerve pain and sensitiveness of the finger, which persisted for months. Some two years after the pain in the finger had disappeared the patient revisited the locality where the whitlow had developed, and for two or three days she experienced the old pain in the finger, which she correctly attributed to the associations attached to her former experience.

Pain may be suggested by the illness of another. We have all met with instances in point. Then, too, pain may develop as a defence mechanism.

A young married woman had a miscarriage soon after her marriage and developed a perineal pain, which made intercourse impossible. A gynaecologist could find no local cause to account for this pain; the patient was in no way averse to intercourse, but inquiry showed that she believed that she was abnormal, and had an exaggerated fear as to the danger of parturition. When she realized that there was no reason for the fears she entertained the pain speedily disappeared.

Pain may be fostered in association with an inferiority complex. An individual recognizes that he is not up to what is required of him, and in some pain or other symptom from which he suffers he finds an excuse which will afford an explanation to the outside world and serve to maintain his self-respect.

We practitioners are apt to be too materialistic in our outlook. We are always searching for something objective to account for pain and other subjective symptoms to which, when found, we can attribute *all* the symptoms, often forgetting the part played by the mental attitude of the patient. Many of us can recall the day when the discovery of a movable kidney afforded us so much satisfaction. Here there was something to account for vague abdominal symptoms and for a neurosis from which the patient was suffering. Was not the proof to be found in the fact that the fixation of the kidney was, in some cases at least, followed by pronounced improvement? We failed for long to realize that by erroneously attributing symptoms to a movable kidney, of the existence of which the patient might be unaware, we were associating in the patient's mind the neurosis with the kidney; that she was only too pleased to have something tangible to which to refer her symptoms; that the movable kidney was in no sense responsible, but that once having produced this association in the patient's mind the symptoms would probably persist so long as the patient was aware of the physical condition which she regarded as their cause.

A lady consulted a surgeon because of abdominal pain, and he diagnosed a movable kidney, which he stitched to the abdominal wall, with the result that the pain completely disappeared. Six months later the patient happened to meet the surgeon. He asked her how she was, and she replied that the operation had been a complete success and that she had had no more pain, but, she said, "for the last day or two I have had a little pain here," pointing to the other side of the abdomen. "Oh," said the surgeon gravely, "I wonder whether the other kidney is loose." The kidney was not palpable, but from that day the patient complained of pain which she attributed to her kidney.

There can be no question but that we often suggest symptoms to our patients by drawing attention to phenomena of the existence of which they had previously been ignorant. Some of us remember the pleasure we used to take in demonstrating a case of hysterical hemiplegia—the loss of pain sensibility, the defective vision, hearing, and smell, the contraction of the visual fields, and so on. All these phenomena were merely indications of suggestibility, and the clinician was often, no doubt, responsible for producing them. When one examines a patient who is obviously suggestible, one does not ask him whether he feels the prick of a pin, but one says to him, "You feel that quite well, don't you?" and his reply is almost always in the affirmative, provided that he has not been previously examined. The man who has *x*-ray photographs taken in cases of visceroptosis and shows them to the patient in order to demonstrate the dropping of the viscera, and impress the patient with his diagnostic skill, is indeed a dangerous fellow, for, while visceroptosis may cause symptoms, it is often symptomless, and the last thing we wish is that the patient should erroneously attribute his discomforts to a physical cause we are unable to rectify.

We are all only too familiar with the pains complained of by the hysterical subject, the individual who believes that others fail to understand, and to give her that pity she feels that she deserves, whose craving for sympathy amounts truly to a vice. The state of mind of the litigant who suffers from pain, which he attributes to his accident, and the desire for material sympathy, is very similar. Impressed by what he regards as the injustice of those who, he believes, are either biased or regard his case from a too optimistic standpoint, he feels he must accentuate his sufferings to make them understood.

A type of case which presents great difficulty in diagnosis is well exemplified in the nervous woman who suffers from chronic abdominal pain. Here it may be extraordinarily difficult to apportion the physiogenic and psychogenic elements. None of us who have read that masterpiece of clinical picture-painting in which Robert Hutchison describes these patients is likely to forget it. "She is a connoisseur in doctors, specialists, and treatments, she has often acquired the operation habit, and although any new therapeutic plan usually relieves her for a time, the relief is always very short-lived." Chronic invalidism might often be prevented if these cases were recognized in their early stages, and, if I may say so without offence, saved from the machinations of a materialistic surgeon who ignores the mental side of the picture, and by plicating the stomach or fixing the dropped bowel—operations which are nowadays fortunately going out of fashion—often merely serves to perpetuate a clinical picture which in many cases, at least, is very largely of mental origin, although no doubt determined in the first instance, as is almost all psychogenic pain, on a physical basis.

If the medical man may be so deceived as to the cause of pain, we can readily understand that the patient may attach a quite erroneous interpretation to this symptom. It is natural that he should associate the pain with an organ which he believes lies in its immediate vicinity. We have all met with patients suffering from lumbago who have come to us under the impression that they must have disease of the kidneys, or complaining of precordial pain which they believe is an indication of cardiac disease, but which is actually due to heartburn.

Misconceptions of the kind are in themselves harmless unless the patient becomes anxious as to the cause of his pain, when a state of introspection may be initiated. This may culminate in an anxiety neurosis, and result in a disability as pronounced and as persistent as that due to grave organic disease. Indeed, as an experienced practitioner recently remarked to me, "an anxiety neurosis wrecks many a man's life." Now an anxiety neurosis is easily produced, and the practitioner is often responsible. If a tendency to introspection is recognized in its early stages it can usually be effectively dealt with, but if it is permitted to become a habit, like all habits it is difficult to correct. One of the most important qualifications of the practitioner consists in his ability to visualize a case from the patient's point of view, to recognize anxieties when these exist, and correct them where this is possible.

Reference to some general diagnostic and therapeutic principles may prove useful in dealing with patients, particularly those who are obviously anxious-minded, in whom pain or other subjective symptoms are predominant. A patient commonly consults a doctor for one of two reasons: on the one hand, it may be that the pain or other symptoms of which he complains are so distressing that they are interfering with his daily duties or his personal comfort; or, on the other hand, it may be that he fears that the symptoms in question, though not severe, are the precursor of illness which may temporarily or permanently incapacitate him or perhaps even prove fatal.

While in the majority of cases pain is attributable to, and adequately accounted for by, obvious physical causes, in some the severity of the pain and its persistence appear to be out of proportion to the physical condition, and in others no physical condition can be detected. In such circumstances the question arises, Is the pain in whole or in part psychogenic, or is the patient wilfully exaggerating or malingering? The answer to this question is often a matter of great difficulty, and an opinion can only be arrived at after a full consideration of all the data. Among these the following are deserving of special mention—namely, the situation and character of the pain, its constancy and intensity and circumstances which appear to influence it; the cause to which the patient attributes his pain, and possible misconceptions on his part which call for correction; the personality of the individual, his behaviour, his surroundings, his suggestibility, and his general outlook on his case; his responsibilities and sense of responsibility; the existence of an inferiority complex, his financial position, and, it may be, the question of compensation and his attitude towards it.

When one examines a patient whose symptoms there is reason for believing are psychogenic, or who, one feels, may be exaggerating, it is essential that the patient should not realize one's suspicion. He should feel, indeed, that one fully appreciates his trouble and sympathizes with him, for it is only by adopting such an attitude that it is possible to gain his confidence. The patient should be examined alone and his story patiently listened to, for the

history is of great importance. Direct questions as to the presence of symptoms of which the patient has *not* complained are to be avoided. A thorough, if rapid, routine examination should be carried out on the first occasion, if only to impress the patient with the fact that nothing has been omitted. Again, as one organ after another is examined, it is advisable to say, "Your heart, at any rate, is quite sound"; "your lungs are quite healthy," and so on, for it must be remembered that the patient may have fears which he has for the moment forgotten to mention, or has purposely refrained from mentioning. If there is evidence of organic disease it is best to tell the patient so; we must take him into our confidence, and explain to him exactly what significance we attach to it. When the opinion is expressed to the patient it must be as dogmatic as the facts permit, there must be no prevarication, and the symptoms to which he attaches special importance must be specially mentioned.

Finally, if no organic disease is found, don't clap the patient on the back and say, "There is nothing the matter with you, old fellow." This, it is true, may be all that is required in some cases, but other patients will go away and say, "By Jove! that doctor would know there *was* something the matter if he had my trouble." No, we must try to give the patient an intelligent and intelligible explanation of his symptoms. If the patient asks whether his symptoms are "imaginary," we must clearly explain to him what is implied by the word "imaginary," that there is nothing to be ashamed of, and that these pains may cause just as much suffering as those due to organic disease. We practitioners, I repeat, are often responsible for creating and perpetuating states of invalidism, either from want of knowledge or want of understanding. It may be that we fail to read the patient's mind and realize his misconceptions; again, we may forfeit the patient's confidence by giving him the impression that since his symptoms are not dependent upon organic disease his condition does not call for special attention, as there is nothing to be done. Even more culpable is the action of the weak man with whom we occasionally meet, who, posing under the guise of a "kind, attentive doctor," follows the path of least resistance, panders to his patient's whims, and unwittingly cultivates a curable neurosis as he would a hot-house plant.

In a last word I would refer to the value of isolation as an adjunct in the diagnosis and treatment of pain in which there is an obvious *psychogenic element*, and in the detection of malingering. Isolation has, in my opinion, fallen undeservedly *into disuse*. I have repeatedly demonstrated its efficacy in hospital practice in this type of case. There are three chief reasons why the "rest cure," as it was called, is nowadays but seldom employed: first, because at one time it was utilized indiscriminately in the treatment of all kinds of unsuitable cases; secondly, because it was often exploited by those who *failed* to appreciate its underlying principles; and thirdly, because the modern psychotherapist *argues that if a patient* is treated in isolation his environment is artificial, and that, although he is thereby protected *during his* course of treatment from counter-suggestion, he will relapse when he is once more let loose in the world. Dejerine, who did more than anyone to popularize this therapeutic measure, held a contrary view. This objection is purely hypothetical, and I know of no evidence to show that it is borne out by fact. Isolation might, I am convinced, be utilized with advantage very much more than at present is the case. It is a most useful adjunct to *suggestion* and persuasion in the treatment of cases of pain in which the psychogenic factor is predominant.

I have spoken of pain, but what I have said is equally applicable to many symptomatic manifestations with which we meet. Our conception of disease must not be limited by the confines of morbid anatomy, clinical pathology, and biochemistry. We are necessarily concerned with *all* those disturbances of function which tend to shorten life and produce incapacity, and with *all* the determining factors which give rise to them. What better illustration in this connexion than the symptom pain, the subject of these remarks?

PERFORATIVE DIVERTICULITIS OF THE COLON.

SOME PROBLEMS DURING THE TREATMENT OF A FATAL CASE.

BY

SIR W. I. DE C. WHEELER,

DUBLIN.

PERFORATION of the pelvic colon into the free peritoneal cavity in the case of an apparently healthy adult is sufficiently uncommon to justify, I think, this short communication.

Discussions on the prediverticular state, the comparatively common condition of diverticulosis, with such sequelae as diverticulitis, abscess and fistula, obstruction, and carcinoma, have received considerable attention in recent surgical literature (Spriggs, Mummery, Mayo, etc.). The case under review is in a different category.

History.

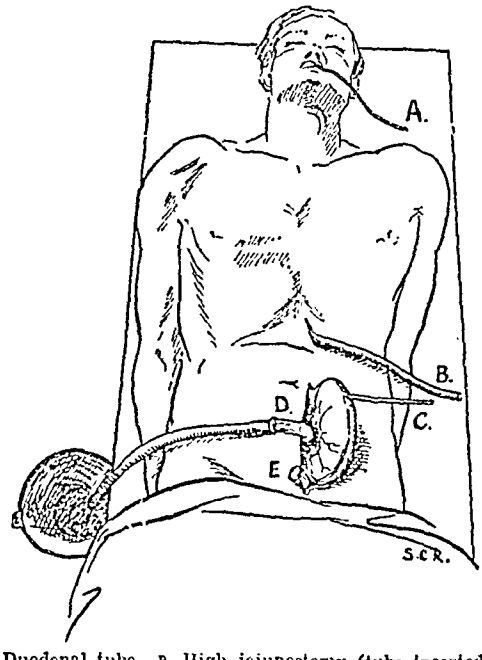
On April 27th last an apparently healthy man, aged 44 years, took a dose of salts in the morning, before breakfast. He had *felt* vague pain and discomfort in his abdomen for some days previously. Within an hour of taking the salts his bowels acted twice. He was *seized with a sudden excruciating* pain in the left iliac fossa after the second motion. He could put *his finger* on the exact spot. He said he felt as *if he had been shot*. He lay down with his legs drawn up, applied hot-water bottles to his abdomen, and drank some brandy, which was at once vomited. He was seen within an hour, and was then in a condition similar to an early case of perforated duodenal or gastric ulcer, except that all the local signs and symptoms were confined to the left iliac fossa. The pulse was slow, the temperature normal. There was fullness and rigidity of the lower abdomen, much more marked on the left side. There was nothing to be felt *per rectum*. The upper abdomen was soft, and high abdominal respirations were still present.

Diagnosis.

The diagnosis presented little difficulty. No left-sided appendicitis could have developed with such dramatic suddenness; the bowels had acted well, there was no distension, the picture was one of acute peritonitis, and not that of an obstructive lesion. In an adult, vigorous and healthy an hour previously, it was difficult to think of any likely cause other than perforative diverticulitis which would produce such an acute condition in the left lower abdomen. The diagnosis was made within a few minutes of seeing the patient. It was recognized that perforation of the colon into the peritoneal cavity, such as occurred in this case, *or in cases above a malignant obstruction*, is followed by a peritonitis of intense virulence, and a grave prognosis was given. (The segment of colon *involved is notoriously septic, and when* there are no limiting adhesions the assault on the peritoneum is seldom successfully countered.)

Operation.

Within three hours of the onset of pain the abdomen was opened on the left side below the umbilicus. So-called pus, *probably* of the defensive and protective variety, welled up. The coils of small intestine first seen were covered already with *patches of protective* lymph. The pelvic colon was sought, and was found loose, boggy, and swollen. The exact site of the perforation was difficult to *locate at first, but* was subsequently found. The friability of the swollen loop was such that an attempt at suture of the perforation was found to be *impossible*.



The exceptional freedom of the coil from adhesions suggested that there never had been previous attacks of diverticulitis, and confirmed a negative history given by the patient. The perforation was dealt with by leaving the loop of colon outside *the abdomen, with* a subsequent Mikulicz resection in contemplation if all went well. The caecum was drained, as it was thought unlikely that faeces could pass *for some considerable time* through the affected loop. It was possible to introduce the caecal tube through the primary incision. The pelvis was also *drained*.

At the conclusion of the operation the stomach was washed out, and, notwithstanding the short space of *time which had elapsed* (three hours) since the perforation, it already contained ominous black material.

After-History.

There was very little drainage from the caecum. On the day *after operation* vomiting became frequent; repeated lavage of the stomach only gave very temporary relief. A stab wound was made in the *extruded loop of* bowel, through which enemata were given without effect. Vomiting continued, and it was soon obvious that

a high obstruction was established, and high jejunostomy was indicated. An incision was made parallel to the left costal cartilages under gas-oxygen and local anaesthesia. A distended loop of jejunum was selected and a catheter was introduced by the usual Mayo method. A few ounces of green fluid came through the tube, but there was no subsequent drainage. Fluid, however, could be freely introduced.

A, Duodenal tube. B, High jejunostomy (tube inserted too low). C, Stab wound in colon. D, Caecal drainage. E, Drain in pelvis.

Vomiting continued throughout the third day. A second jejunostomy after identification of the flexure was considered, but it was felt that the same result might be obtained by drainage of the stomach and duodenal contents through the medium of a duodenal tube. The tube was swallowed with great difficulty between two attacks of vomiting, and, after lavage, by means of a nasal tube. It was now possible to aspirate fluid every half-hour with a Record syringe. Three pints were withdrawn in twelve hours. The character of the fluid completely changed; at first it was black, afterwards it became orange-coloured, with a foul, but not a faecal, smell. The toxicity of this fluid was made evident by the fact that if aspiration was delayed on any occasion the condition of the patient became rapidly worse.

The mechanical difficulties encountered were dealt with in the manner indicated, but, in addition, it was necessary to cope with progressive failure of strength from toxaemia and loss of fluids.

Biochemical Considerations.

Every few hours a pint (12 pints in all) of 10 per cent. glucose solution in distilled water was administered intravenously. During and at the end of each transfusion insulin was given hypodermically (1 unit to 3 grams of glucose). Fluids were given continuously by the drop method into each axilla; water, peptonized milk, and panopepton were introduced through the jejunostomy tube. It was interesting to note that, immediately after a transfusion, duodenal regurgitation increased, necessitating aspiration on each occasion.

At one stage the urine became alkaline, dehydration was marked, and slight tetanic spasms (cramps) occurred in the arms, suggesting the condition of alkalosis so commonly observed in the presence of high obstruction. Improvement followed the administration of collosol calcium and the substitution of hypertonic (3 per cent.) saline solution for distilled water when administering the glucose.

Towards the end of the illness a dilemma arose in connexion with treatment. Duodenal contents in the presence of high obstruction are notoriously toxic. Their retention is fatal. On the other hand, if they are abundant and freely drained the patient cannot survive their loss for any prolonged period. After forty-eight hours of frequent aspiration through the duodenal tube the patient became dehydrated and stuperose, and threatened with a physiological death.

Wilkie of Edinburgh was confronted with a similar dilemma in somewhat similar circumstances. High obstruction followed appendicectomy; the jejunostomy opening was made too low. A second jejunostomy was performed at a higher level. After a period of free drainage rapid emaciation followed and death appeared imminent. The upper and lower jejunostomy tubes were connected outside the abdomen so that the duodenal contents could be delivered into the lower intestines. An immediate improvement in the condition of the patient followed, with ultimate recovery.[1]

Wilkie's method was adopted in the present case in a modified form. The duodenal contents, immediately on their withdrawal, were injected through the jejunostomy tube with an aspirating syringe. Coincidently with this procedure the caecum commenced to drain. It was noticed that the peptonized milk, panopepton, and other materials given via the jejunostomy opening passed through the caecal tube unaltered.

Termination.

With the caecum draining and the duodenal contents saved the general condition of the patient improved. On the morning of the fifth day he announced that he felt better and was going to recover. The Record syringe failed to find any fluid in the stomach and duodenum, and some bile appeared for the first time in the caecal drain. The bile was green, and not intermixed with the other faecal material. (This has been noticed in other patients suffering from pancreatic disease.)

For six hours the patient made rapid strides towards recovery; there was no further regurgitation into the duodenum; his appearance was transformed. He was given a hypodermic of omnopon to promote rest, and all who were watching him felt that at last recovery was assured.

On the evening of the sixth day the signs of high obstruction again appeared; restlessness and delirium quickly followed. Aspiration of the duodenal contents and intravenous medication gave no response. He died twelve hours later.

Towards the end of the illness respirations became fast without any pulmonary complication; air hunger was followed by the appearance of acetone and diacetic acid in the urine. Alkalosis had now given place to acidosis. Alkali solutions, rigidly avoided at first, were freely administered in combination with glucose, but without effect in the end.

A post-mortem examination was refused, but the loop of bowel was examined, and proved to be the site of perforative diverticulitis.

The following points in the case are noteworthy.

1. The ease of diagnosis.
2. The good fortune in finding the perforation in a loop of bowel easily extruded.
3. The free drainage of the caecum after some days, with complete emptying of the lower coils of intestine in the presence of persistent high obstruction.
4. The efficacy of the retained duodenal tube as a means of high drainage.
5. The extreme toxicity of the obstructed duodenal contents.
6. The signs of hepatic and pancreatic insufficiency in the presence of continued obstruction.
7. A condition believed to be alkalosis changing to acidosis.
8. The dramatic relief from obstruction followed by a fatal relapse.

In conclusion, I wish to acknowledge my great indebtedness for the untiring help of Dr. Magennis and Dr. Gilbert Wilson in the management of the case. Dr. T. T. O'Farrell kindly examined and made sections of the specimen removed after death.

THE EARLY DIAGNOSIS AND TREATMENT OF CANCER.*

BY

MALCOLM DONALDSON, F.R.C.S.,

PHYSICIAN ACCOUCHEUR, WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL.

In his opening remarks Mr. Donaldson suggested that the problem of cancer might be considered under four headings: etiology, early diagnosis, treatment, and education of the public, and, having described briefly some of the views held on the etiology of cancer and indicated lines on which further investigation is proceeding, he continued as follows.

My object now is to discuss the second, third, and fourth parts of the problem, and it is as well to begin by trying to picture the situation as it exists to-day. To do this, I will try and describe what happens to thousands of people each year.

First, there are the average men and women, going about their daily life, occasionally thinking of the question of cancer. One day they experience some perplexing

* Abstract of an address delivered at the Royal Institute of Public Health on November 20th, 1929.

symptom; it is not a symptom that they are used to; they cannot assign any definite cause, such as a blow. They immediately think—Is it cancer? They try to put it out of mind; they put off going to their medical adviser for fear that he may pronounce it to be malignant disease, then later on they are forced to seek medical advice. They do not go and say: "Look here, I want to know whether I have cancer," but they go and give a general story, sometimes actually hiding the main symptom, hoping in their hearts that the doctor will realize they are nervous of cancer and tell them that they have not got it. It is an interesting psychological fact that people fear to admit they are afraid.

Then we come to the average practitioner; he is perhaps unable at a first glance to find out exactly what is the matter with this particular patient, but it is obvious that it is not an acute condition, so he recommends a bottle of medicine and a little rest, and tells the patient that if he does not feel better to come and see him again. The patient, consciously or subconsciously, takes this to mean that he has not got any malignant disease, and he does not feel ill enough to repeat the visit. A few months later, however, the symptoms are much worse, and he goes to see his practitioner, who now has no difficulty in seeing what is the matter. But precious time has been lost, and the chances of curing the patient are very much less. Yet no one is to blame; it is the system that is to blame. Many times have I had a letter from a doctor saying: "I have treated Mrs. X on and off during the last six months for toothache, indigestion, or what not, but only yesterday did she tell me that for the last nine months she had noticed irregular haemorrhage. When I knew this I at once examined her, and now send her to you, as I fear she has got an advanced cancer."

Then we come to the last part of our story—the present state of treatment of cancer. That is left largely in the hands of experts, but even here things are not satisfactory. The number of cases that can be dealt with by the experts is very limited, and naturally the early cases are given preference, as their chance is better. To get their patients treated quickly general practitioners have, therefore, to send many of them to general surgeons, who perhaps are rather less experienced in the treatment of malignant disease. It is becoming more and more common to find in the smaller country towns such general surgeons attached to a firm of general practitioners, and it is obvious that the combination is of very great value to the community, but for the particular object of cancer treatment such surgeons cannot have sufficient experience to be really up to date.

That, then, is a fair picture of the present state of affairs.

It would be as well now to consider, first, what should be the ideal, and, secondly, how any system can be grafted on to the existing one. Who is the first professional person to come in contact with the patient? Obviously, the general practitioner. He, therefore, is the keystone to an arch on which all the rest depends. One of the primary thoughts he must have in his mind when a patient comes to see him is, Has this patient got early malignant disease? Can every practitioner be made an expert in diagnosis of cancer? The answer is undoubtedly, No. He can only suspect the possibility that from the symptoms the patient may have malignant disease, and then at once send the patient to a diagnostic centre. Now what is needed in these diagnostic centres?

First, there is the question of the staff. This staff must be a well-organized team, trained in the science of cancer diagnosis. This is where we meet with the first difficulty. It is essential that the centres should be so plentiful that patients do not have to travel far from their homes in order that a diagnosis can be made, and yet these preliminary centres need highly skilled staffs, including surgeons, radiologists, and pathologists, and other specialists. Though it is not easy to find a number of such teams, nevertheless it should be possible to find one in each county hospital.

If it is discovered that the patient is suffering from malignant disease he or she must at once be transferred to a centre for treatment. These centres should be relatively few. Any person should be able to get a diagnosis made without any appreciable interference with his daily life; but treatment centres cannot be efficiently and economically run except in large institutions. The question arises—how to staff these large institutions. The staffs must be people who devote the greater portion of their lives to treatment of malignant disease; they must also act as a team, and frequent consultations should be held between the surgeons, specialists, radiologists, physicists, and pathologists. Such institutions must not only be for the treatment of the individual patient, but centres for education and research into treatment: post-graduate courses, both in treatment and in diagnosis, should be frequently held.

Patients who have passed through such a centre must be under its foster-care for the remainder of their lives, and for this purpose the centre would need an efficient follow-up department, which would write and ask the patient to come up to be examined at frequent intervals. There should be also a social service attached, which knows what happens to incurable patients. Much more could be done than is done at present for relieving pain in these cases. How many surgeons interested in neurology have worked out methods for destroying the pain-conducting nerves, yet it is not difficult to imagine operations for dividing the posterior roots, which, though not prolonging life, would make the last months more bearable.

Now we come to the last part of the problem, but by no means the least—namely, *the education of the public*. If we are successful in solving this all the rest of the difficulties will disappear. There are a few people who say that if we tell the public all about malignant disease a generation of neurasthenics will be produced who will go about imagining that they are suffering from cancer. Nothing, however, is further from the truth. There are millions of people who now spend hours of agony fearing that they have this dread disease, and if they could once summon up courage to go to a centre and be told that they have *not* got *malignant* disease they would go away quite happy. It must be the common experience of most practitioners, *certainly of gynaecologists*, that patients come complaining of some indefinite symptom. When, after careful examination with negative results, patients are told that there really is nothing serious, no tumour or cancer, etc., an expression of relief at once comes over their faces and they admit that that is what they had been fearing.

Until recent years tuberculosis claimed as many deaths as cancer, but very few people suffer from apprehension that they have tuberculosis. And why? Because they talk about it; because they know some of the symptoms; because they are not frightened or ashamed to go to a doctor and say: "I want you to go over my lungs and see that I have not got consumption." It may be said that there is another reason—namely, that consumption is curable; but so is cancer, if taken early enough. At present nine out of every ten people believe that no patient is ever cured of cancer. It therefore may be said that the first great step towards education is to make people talk more about it.

The next step is to get reliable facts published concerning the disease, and here I would appeal to the newspapers to go to committees for their articles on cancer rather than to individuals, whose object is often to promote their own welfare rather than that of the public. I am afraid this suggestion will not appeal to the less reputable organs of the press. It is much more exciting to have a headline such as "Eating tinned lobsters is the cause of cancer," than to publish a carefully thought-out article which has been discussed and passed by a committee of experts.

There are some who may say that the symptoms are so insidious and so often common to other conditions that it would be unwise to broadcast that these symptoms are possibly the early warnings of cancer; but, after all, the majority of people do not suffer from any symptom and will not be worried by such knowledge. To quote one small instance, in the case of women the two common sites for cancerous growth are the breast and the uterus. If every woman knew that the absence of any lump in the breast meant that she had not got cancer of the breast, and the absence of any irregular vaginal haemorrhage meant that

she had not got malignant disease of the uterus, it would relieve thousands of women of a haunting fear. Conversely, they should be told that if they have a lump in the breast they must at once consult a doctor, and likewise if they have *any irregular* haemorrhage. When, however, such propaganda is sent out it should also be explained that not every lump in the breast is cancer, and that a great many cases of irregular haemorrhage are not due to this serious condition.

It has been suggested that it is a good thing to tell the public the statistics of people dying from malignant disease. It is often said that cancer is on the increase, a statement which, though probably true, is by no means as true as the figures would seem to suggest. We must allow for the greater age to which people live, and for the better diagnosis owing to the higher average diagnostic ability of the general practitioner compared with that of a past generation. But how is broadcasting these facts going to help the public?

There is, however, one thing that will appeal to the people, and that is their pocket. Few of us are really very frightened of dying; most of us dislike the idea of pain during the process of dying; but all of us fear being put out of action and seeing our relatives suffering because the breadwinner is laid low and additional expenses are being incurred for treatment. Can this expense and worry be avoided, and can any scheme for this object be made to help in the education of the public? I believe it could be if a special insurance policy could be taken out for cancer, and if the premium on such a policy could be reduced on the production of a certificate that the individual had been examined within the last six months and shown to be free from any signs of malignant disease. Such a system would, I venture to suggest, appeal to millions of people. It is true that the insurance companies are not primarily philanthropic societies, and inquiries suggest that they are averse to the principle of frequent medical examinations in connexion with insurance. On the other hand, if a case of cancer is treated early the prospects of a permanent cure are very good, and the patient will go on paying premiums for a great many more years, and the insurance companies will not have to pay the large sums of money which are forfeited on the death of the patient.

There is yet another line in which the public must be educated, and that is concerning the meaning of the word "research." Nine out of ten people, even among the better educated, believe that research means that a person suddenly thinks of an experiment and does something to see what will happen, much in the same way as a little boy will put a match under some gunpowder to see what comes next. Nothing is further from the truth. Research may be considered under two headings: first, laboratory research; secondly, clinical research. Both of these are essential if any advance is to be made in the fight against cancer; but it is about the clinical side of research that the public must learn.

If we labelled any hospital as a "Research Hospital" it would be very difficult to get patients to come and be treated. The patients would imagine that the surgeon, like the little boy with the gunpowder, is going to do an experiment not knowing in the least what will happen. What are the real facts? In clinical research a patient is treated by the most up-to-date methods known to science, but instead of letting that patient go out of the hospital and all the facts concerning him be forgotten, extremely careful notes are taken before the treatment is started, during the treatment, and after the treatment. When some hundreds of similar cases have been treated these notes are collected and carefully compared to see the value of such treatment or the value of any modification that has been made in that treatment. It is true that to a greater or lesser extent all hospitals are research hospitals, because experience is gained by somebody every time a patient is treated, but in a busy general hospital the need to treat thousands of patients as quickly as possible prevents the medical attendant from making as careful records as is desirable. For that reason it is far better to segregate patients suffering from cancer in special hospitals, the staffs of which are specially chosen for their interest in and knowledge of that disease. Such a hospital must lay itself out for the careful observation and making of records.

It is quite true there are in this country cancer hospitals, but are there sufficient? There are in the British Isles over 40,000 deaths from cancer every year, and every one of these cases should have careful records and special investigations if rapid advances are to be made in the treatment of malignant disease. Can the existing hospitals deal with such numbers? It is obviously absurd. Even if there was sufficient accommodation in the existing hospitals, I venture to say that there is not one single hospital which at present quite "fills the bill" as a research centre. It is our duty to demand that such centres be created. Every such centre should have an efficient and well-equipped research laboratory attached to it so that clinical research and laboratory research can go hand in hand. It must not be forgotten that it is the patient who is suffering from the disease, and it is the patient who must be cured.

There is yet another difficulty that the public cannot realize—namely, that progress is a matter of evolution. One point gained leads to another, but the final goal is often a long way off, and it must be a really philanthropic person who is prepared to put down money to help a cause the ultimate goal of which may not be reached until after the death of the donor. If one could guarantee to have a solution to the problem within a specified time there would be no difficulty in getting money, but that is not possible. But think of the magnificent gamble! By subscribing a million or even half a million to a hospital the goal may be reached within a comparatively short time.

UNION AND NON-UNION OF FRACTURES.

WITH SPECIAL REFERENCE TO FRACTURES OF THE NECK OF THE FEMUR IN ELDERLY PEOPLE.

BY

A. S. BLUNDELL BANKART, M.CH., F.R.C.S.,

ORTHOPAEDIC SURGEON, MIDDLESEX HOSPITAL.

(*With Special Plate.*)

IN most situations in the body fracture of a bone is normally followed by a process of repair which leads eventually to restoration of the continuity, strength, and rigidity of the broken bone. This is bony union. Failure of bony union is non-union, because no other kind of union can give the strength and rigidity which are essential to the normal functioning of a bone.

For the purposes of this inquiry it matters not whether the fibrous tissue between the fragments of an ununited fracture is thin and loose or thick and firm, nor whether the ends of the fragments themselves are atrophied and pointed or enlarged and shaped to the semblance of a joint (pseudarthrosis). It is sufficient that non-union as a rule causes great disability, so that bony union is the ideal to be aimed at in the treatment of nearly all fractures.

The causes of non-union given in textbooks of surgery are many and various, and the following classification is fairly typical of them all.

I. Local causes:
   - (*a*) Imperfect immobilization—said to be the most frequent of all causes.
   - (*b*) Great separation of the fragments.
   - (*c*) Interposition of bone, muscle, or tendon.
   - (*d*) Poor blood supply through injury of the nutrient artery—for example, in fracture of the neck of the femur.
   - (*e*) Tumours—sarcoma in callus or pathological fracture through tumour.
   - (*f*) Infection and excessive suppuration.

II. General causes—for example, acute infectious diseases, scurvy, syphilis, osteomalacia, gout, rickets, rheumatism, chronic nephritis, diabetes, alcoholism, anaemia resulting from prolonged lactation or long-continued fever.

Before commenting on these alleged causes I would suggest that there is really only one common cause of non-union—namely, absence of haemorrhage between and around the fractured surfaces—and that the great majority of the causes given above may be identified with it.

The bones in most situations are vascular, and bleed when they are broken. Usually there is considerable haemorrhage between and around the fractured surfaces, and the extravasated blood, acting as an irritant, provides the first stimulus to repair of the fracture. Absorption of the blood clot and its replacement by connective tissue cells derived largely from the periosteum and marrow of the broken bone is the first step in the formation of the provisional callus which is essential for bony union.

When for any reason sufficient haemorrhage does not occur at the site of a fracture, the natural stimulus for repair is lacking, and the fracture may fail to unite. This event is especially common in the case of fracture of the neck of the femur in an elderly person, not, as usually stated, on account of malnutrition of the fragments, but simply on account of the absence of haemorrhage, for these fractures are practically dry.

Many surgeons, and particularly those who are familiar with cranial surgery, are aware of the remarkable haemostatic effect of fresh muscle tissue when it is applied directly to a bleeding point or surface. In some cases, when a bone is broken, the jagged broken surfaces are immediately thrust into the mass of muscle surrounding them. Haemorrhage is thus arrested, and when eventually the fragments are reduced and brought into apposition there may be little, if any, blood clot around them to provide the stimulus for repair. It has occurred to me that this may be the explanation of some cases of non-union—for example, of fractures of the shaft of the humerus.

When a fracture is compound and infected, even mildly, the first effect of the suppuration is to break down and remove the surrounding blood clot, which is discharged as pus. The infective process, if mild, may itself provide the stimulus for repair; but, on the other hand, it may not, and this is a not uncommon cause of non-union.

Of other causes of non-union, imperfect immobilization is said to be the most frequent of all. This is absolutely untrue. The treatment of fractures by active movements from the first results in sound bony union. Deliberate attempts to prevent bony union by active or passive movements are frequently unsuccessful. Fractures of the ribs and other bones, both in man and in other animals, unite readily in spite of constant movement. Great separation of the fragments, as well as the interposition of soft parts, may make it mechanically impossible to restore the continuity of the bone.

Poor blood supply through injury of the nutrient artery suggests that the reparative power of the bone is interfered with. But I would again suggest that the real cause of non-union is absence of stimulus, due to insufficient haemorrhage. Tumours, in so far as they are purely destructive, are an obvious cause of non-union.

Turning now to the general causes of non-union, many of these—for example, syphilis, gout, chronic nephritis, diabetes, and chronic alcoholism—are conditions which are or may be associated with arterial disease (endarteritis, arterio-sclerosis), and it is possible that this may account for very slight bleeding from the ends of a fractured bone, and in exceptional cases lead to non-union. It is difficult to see any other connexion between these common conditions and the comparatively rare occurrence of ununited fracture.

No orthopaedic surgeon would accept rickets as a cause of non-union. Deliberate fracture of rachitic bones for the correction of deformity is one of the commonest orthopaedic operations, and non-union is practically unknown. On the other hand, so-called renal rickets, which has nothing to do with rickets proper, but is definitely associated with chronic nephritis and arterial disease, may be included in the causes of non-union. Osteomalacia is not a cause of non-union, and I know nothing of non-union due to rheumatism, scurvy, or acute infectious diseases.

I would submit that there is only one common cause of non-union of fractures, and that is insufficient haemorrhage between and around the fractured surfaces. Two practical deductions obviously follow this conclusion: (1) that in order to promote union there must be blood clot at the site of a fracture; and (2) that in order to prevent union haemorrhage must be prevented, and blood clot, if present, must be removed.

Intracapsular Fracture of the Neck of the Femur.

Until comparatively recent times non-union was thought to be the almost inevitable result of an unimpacted intracapsular fracture of the neck of the femur. Non-union in this case has been attributed to malnutrition of the head of the bone, or to lack of apposition of the fractured surfaces (Whitman). More recently numerous attempts have been made to secure bony union in this fracture (*a*) by operative fixation of the fragments, (*b*) by the abduction treatment of Royal Whitman, and it is now pretty well established that bony union may be obtained in a fair proportion of cases by either of these methods.

But, while each has its enthusiastic advocates, neither method is suitable for general application among elderly patients. Intracapsular fracture of the neck of the femur is one of the common fractures of old people, and though it is true that it occurs also in the comparatively young, and sometimes even in the very young, this does not alter the fact that the majority of cases met with in practice are at least middle-aged or elderly. Many of these are entirely unsuited for direct operative intervention on the hip-joint, and the same objection applies to some extent also to the abduction treatment of Whitman.

The abduction treatment is by no means a trivial affair. For an elderly patient the administration of an anaesthetic, the forcible manipulation of the already injured hip, the application of the plaster, which takes time, and the prolonged fixation of the patient in plaster afterwards, constitute an ordeal which is not likely to become standard or routine unless we can confidently predict bony union as the ultimate reward. This we cannot do. The only statistics available show failure of bony union in from 30 to 40 per cent. of cases, and this is the experience of most surgeons.

The outstanding criticism of the abduction treatment, however, is that it is purely mechanical and takes no account of the physiology of repair in fractures. In other words, Whitman places the fragments in apposition and hopes that they will unite. Sometimes they do, and sometimes they do not. He does nothing further to promote their union, and it may be remarked in passing that prolonged fixation in plaster generally conduces to atrophy of bone, which is not encouraging to union of a fracture.

In the first part of this paper I have put forward the view that absence of haemorrhage between and around the fractured surfaces is the one common cause of non-union. In fracture of the neck of the femur, especially in old people, there is very little bleeding from the bone, and therefore the natural stimulus to repair of the fracture is wanting. Intracapsular fractures fail to unite because they are dry; turn them into wet ones, and they will unite like other fractures. Acting upon this hypothesis we have injected fresh blood directly into the hip-joint as soon as possible after the receipt of the fracture, with the result that sound bony union has been obtained without operation or prolonged fixation of the patient in plaster.

Needless to say, length and alignment are important mechanical considerations, and we have considered the best means of securing proper reduction of these fractures in the circumstances of elderly patients. We do not doubt that manipulation under an anaesthetic is most effective, but we have found that perfect reduction may also be obtained by weight extension, which is far more generally applicable to elderly patients. Weight extension is, of course, one of the oldest methods of treating fractures, but until the introduction of skeletal traction I believe it was not possible to apply really efficient traction to a fracture at the hip-joint. With skeletal traction perfect length and alignment can be obtained. Up to the present time only one case has been treated to a termination.

A woman, aged 57, fell and was admitted to the Middlesex Hospital on March 29th, 1929. On examination she was found to have a typical intracapsular fracture of the neck of the left femur (Fig. 1). Within an hour of her admission 14 c.cm. of blood were injected into the hip-joint. The blood was drawn directly from the median basilic vein with a Record syringe, and injected straight into the joint above the great trochanter. After the injection ice-tong callipers were applied under local anaesthesia to the lower end of the femur, and a weight of 15 lb. was applied at once. The weight was rapidly increased

up to 30 lb., and later reduced to 21 lb. This gave perfect reduction of the fracture with restoration of the normal length and alignment of the neck of the femur (Fig. 2), and it was maintained continuously for thirty days. The weight was then reduced to 11 lb., which was kept on for a further period of fifteen days, and then removed. During extension the limb was slung in a bent calliper splint for convenience in nursing and to reduce friction, but no attempt was made to immobilize the hip—in fact, massage was started at once on all accessible parts of the limb and movements were encouraged as far as possible without disturbing the extension. At the end of nine weeks the patient was got up in a walking calliper splint. For the last two months she has borne weight upon the joint, and she has now discarded the splint. The radiogram (Fig. 3) shows that the length and alignment of the neck of the femur have been maintained and that there is unmistakable bony union.

I am greatly indebted to my Registrar, Mr. E. W. Riches, F.R.C.S., for his invaluable assistance in carrying out the practical details of this case.

Commentary.

All our experience of fractures in general points to the conclusion that mere apposition and immobilization are not the vital factors in the repair of bone, but that a physiological process is involved, and it should be the aim of treatment to stimulate and promote physiological union when this is likely to be deficient. The case here cited was a typical intracapsular fracture of the neck of the femur in a middle-aged woman, which would almost certainly have failed to unite under ordinary treatment by weight extension alone. The injection of fresh blood provided the stimulus to repair, which is present in most fractures, even in old people, but which is lacking in intracapsular fractures of the neck of the femur. Perfect reduction of the fracture was obtained by efficient traction without serious disturbance of the patient, no general anaesthetic or direct manipulation of the fracture being required at any stage of the treatment.

If the experience gained in this case is borne out by others, it seems likely that this treatment by injection and traction will become the method of choice in the future, for it is applicable to any patient who can be kept in bed at all, and, provided that skilled nursing is available, the technical difficulties are not great.

RENAL CALCULUS ASSOCIATED WITH A SOLITARY CYST OF LEFT KIDNEY.

BY

J. C. AINSWORTH-DAVIS, M.A., M.B., B.Ch., F.R.C.S.,

SURGICAL REGISTRAR AND SURGICAL ASSISTANT TO THE UROLOGICAL DEPARTMENT, ROYAL WATERLOO HOSPITAL.

With Operation Note by

T. P. DUNHILL, C.M.G., M.D.,

ASSISTANT DIRECTOR OF SURGERY, ST. BARTHOLOMEW'S HOSPITAL.

(*With Special Plate.*)

THE following case is published for three reasons: (1) To place on record a case of solitary cyst of the kidney (itself a rare condition) associated with a renal calculus, a combination believed to be unique. (2) To describe how a case of renal colic should be relieved, investigated, and treated. (3) To show that, in spite of modern methods of urological diagnosis, the cause of a patient's symptoms may sometimes be only discoverable at the time of operation.

S. T., male, aged 54, married, was seen for the first time on June 8th, 1929, two hours after the beginning of a typical attack of left renal and ureteric colic.

Past History.—Six to four years ago he had attacks of pain in the left side of the lower abdomen which had a sudden onset, a duration of six to seven hours, and an abrupt termination. Four to two years ago there was a period of freedom from attacks. During the last two years there had been several attacks of a similar nature, but not so severe; during one of these a little blood was passed per urethram. A course of waters at Carlsbad made no difference to the symptoms. His last attack occurred about a month previous to the present one, and lasted for four hours. The pain, of a dull aching character, began in the left renal region, with intermittent acute pains shooting to the left testis and tip of the penis. The patient had never noticed any grit in his water. X-ray examination a year ago was said to be normal.

Examination showed the patient to be a healthy well-covered man, but in considerable pain. He micturated four or five times during the day, but not at all in the night; the stream was good and there was no difficulty, urgency, or haematuria. The pain was that of left renal and ureteric colic. The bowels were regular, and there was never any blood or mucus in the stools. Per rectum, the prostate seemed normal; no abnormality was felt. Examination by the abdomen showed neither kidney to be palpable. There was tenderness on deep pressure in the left loin.

Cystoscopy (under local anaesthesia).—The bladder mucous membrane showed mild cystitis with very slight swelling of the left ureteric orifice. A No. 4 Charrière ureteric catheter was passed up to the pelvis of the left kidney. Some resistance was felt at two points: (1) at the uretero-pelvic junction, and (2) about 3 inches lower than this. Some 15 c.cm. of urine, indicating a slight degree of hydronephrosis, were collected and preserved for examination. Immediately the catheter reached the pelvis of the kidney and the flow of urine was established, the renal colic subsided, and after withdrawal of the cystoscope and catheter the patient said he was absolutely free from all pain or discomfort.

A report on the catheter specimen from the left kidney stated it to be of normal colour, acid, slight haze of albumin present, no sugar, no phosphates, and a small deposit of mucus.

Subsequent Progress and Further Investigations.—On radiography of the urinary tract by Drs. Coldwell and Allchin the right urinary tract was found to be normal. The left urinary tract, with opaque catheter passed to the left kidney, showed: (1) no shadow indicating stone in left kidney or ureter; (2) displacement of kidney shadow upwards by a spherical body some 4 inches in diameter which is probably attached to the lower pole of the kidney and moves with it on respiration (Figs. 1 and 2); (3) this body displaces the lower ureter inwards and forwards, causing marked kinking of the catheter on full inspiration (Fig. 3), its opacity to x rays being rather less than that of the kidney itself.

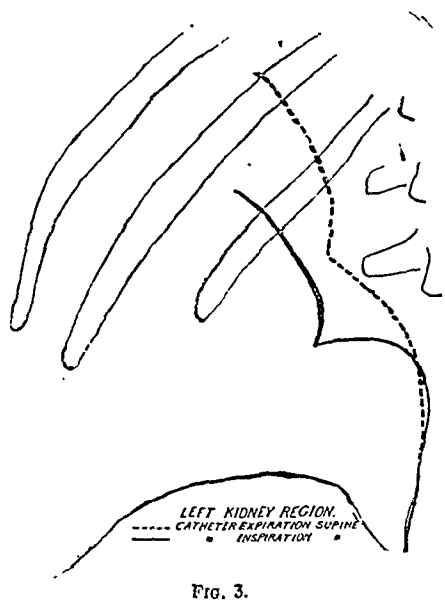

FIG. 3.

Left Pyelogram (with 20 per cent. solution of sodium iodide).—Pelvis and calyces normal. No demonstrable communication with any possible cavity in the spherical body. Sodium iodide withdrawn and a further skiagram taken in the hope that if a stone were present some of the fluid would adhere to its surface and thus throw a faint shadow. No shadow was seen.

Renal Function Tests.—10 c.cm. of a 1 per cent. solution of indigo-carmine were injected into the median cephalic vein, an observation cystoscope being in position. This appeared at the right ureteric orifice in two and three-quarter minutes, the efflux being well stained. There was no appearance of the dye at the left ureteric orifice in twelve minutes.

On June 26th the patient had a second attack of left renal colic, accompanied by some intestinal obstruction and followed by the passage of large quantities of flatus. A catheter was passed to the pelvis of the left kidney and the colic was relieved. The following day, at 9 p.m., he had a third attack of colic. A catheter was passed at the patient's residence, with immediate relief after withdrawal of 15 c.cm. of urine. During this attack it was possible to palpate a tumour in the left upper abdomen.

On June 29th the patient was seen in consultation with Mr. T. P. Dunhill, and the past history and investigations were explained. At this time no tumour could be palpated. Exploratory operation, with differential diagnosis of (*a*) a solitary cyst springing from the lower pole of the left kidney, and (*b*) hypernephroma, was advised, and permission obtained to remove the left kidney if necessary. The renal colic was thought to be due to kinking of the ureter by pressure of the tumour.

OPERATION NOTE BY MR. T. P. DUNHILL.

On June 31st the left kidney was explored through a curved incision in the loin, and on palpation the upper half appeared

FIG. 1. Intracapsular fracture of neck of left femur, before treatment.

FIG. 2.—The same case—showing reduction by skeletal traction.

FIG. 3.—The same case six months later—showing bony union.

J. C. AINSWORTH-DAVIS RENAL CALCULUS WITH SOLITARY CYST OF LEFT KIDNEY.

FIG. 1. Skiagram at full inspiration. Lower margin of cyst below iliac crest. No calculus visible.

FIG. 2. Skiagram at full expiration. Lower margin of cyst well above iliac crest. No calculus visible.

FIG. 4.—Skiagram of kidney, cyst, and calculus after removal. The last is well shown.

[THE BRITISH MEDICAL JOURNAL

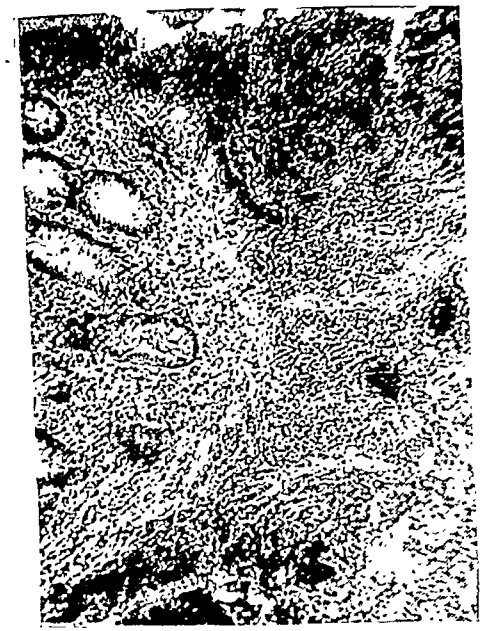

FIG. 1.—Case i. (× 90.)

FIG. 2.—Case ii. (× 25.)

FIG. 1.—Showing triangular shadow within the cardiac shadow.

FIG. 2.—Triangular shadow absent. Lipiodol showing no evidence of bronchiectasis.

FIG. 3.—Showing the triangular shadow with bronchiectasis within it.

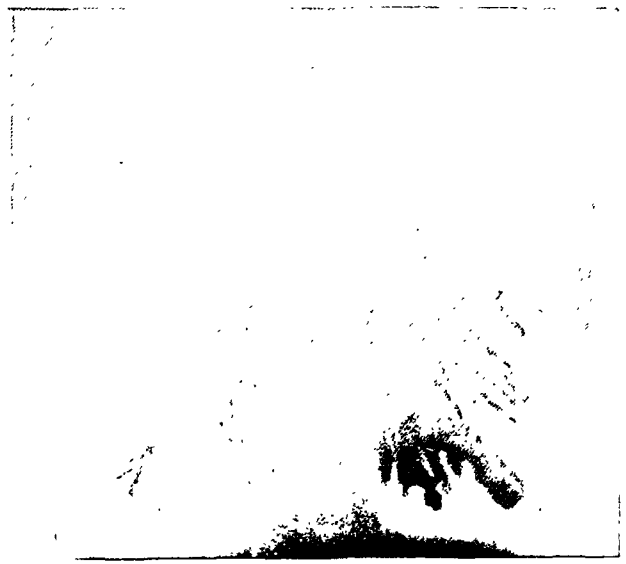

FIG. 4.—Showing bronchiectasis within the triangular shadow.

FIG. 5.—Showing triangular shadow at right base.

normal. The lower half was replaced by a cyst. A calculus about three-quarters of an inch long by half an inch wide was felt in the pelvis. The kidney was removed.

Report on Kidney and Cyst after Removal.

Fig. 4 is a skiagram of the specimen. The calculus is clearly shown. No connexion between the pelvis of the kidney and the cyst could be demonstrated. It would appear that the stone and cyst were independent of each other. The calculus was composed of pure uric acid.

Post-operative Progress.—The patient made an uneventful recovery. When seen on October 11th he was feeling well, putting on weight, and had no urinary symptoms. The urine was normal in colour, acid, clear, specific gravity 1018; no albumin, no sugar; urea 2 per cent.; there was a deposit of mucus. The centrifuged deposit showed an occasional pus cell, some epithelial cells, and phosphate crystals. No organisms were seen. Cultures were sterile.

CONCLUSIONS.

1. The passage of a ureteric catheter to the pelvis of the kidney, and withdrawal of its contained urine, will give immediate (but temporary) relief to pain arising from renal colic.

2. Repeated attacks of renal colic in an otherwise healthy person, even with a normal renal skiagram, should lead to a provisional diagnosis of stone, because a calculus of pure uric acid throws no shadow with x rays, as its consistence is equal to that of the kidney itself. The wax-tipped ureteric catheter should be of some assistance in confirming such a diagnosis where a calculus with a rough surface is present. It was not employed in this case because it was erroneously supposed that the cyst was the cause of the colic. Further, the patient should be advised to undergo an exploratory operation before the kidney becomes too disorganized to be worth preserving.

3. As regards the relations of the stone to the cyst, no connexion of any kind could be demonstrated.

4. Doubtful renal swellings should always be explored, owing to the impossibility of exact diagnosis.

5. Renal tumours can reach a considerable size—for instance, that of an orange—without being palpable in a well-covered patient, and further examinations such as radiography, pyelography, etc., should never be omitted when upper urinary symptoms are discovered.

6. Positive evidence should always be obtained of the presence and function of the opposite kidney in case nephrectomy has to be performed at the time of operation.

TWO CASES OF ACUTE SYPHILITIC APPENDICITIS.

BY

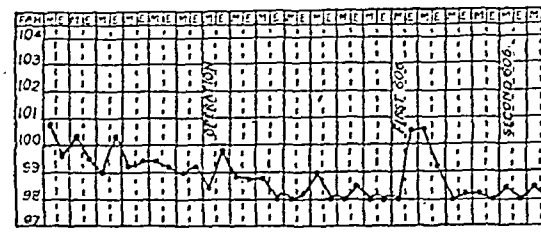
GRIFFITH EVANS, M.A., D.M.Oxon., F.R.C.S.,
CARNARVON;
AND
ELWYN ROWLANDS, M.B., CH.B.
PENYGROES.

(*With Special Plate.*)

THE increase in visceral syphilis is one of the features of medicine in the present century, but up to now not many cases of acute syphilitic appendicitis have been reported. In searching for such records we have had the able and generous help of the librarian of the British Medical Association, but have succeeded in finding two only—those reported by Pasqualis (D. A.).[1]

In Royster's exhaustive monograph on appendicitis (Appleton, 1927) there is reference to pseudo-appendix associated with secondary syphilis. This condition is classed by Condamin and Voron (ibid.) with the form of intestinal neuralgia which Fournier had called syphilitic typhosis.

The two cases about to be described, however, are true acute inflammations.



CASE I.

A woman, aged 19, felt well until she had a miscarriage in the fifth month on the floor of a farm kitchen. During the following week she developed lower abdominal pain and tenderness with pyrexia.

On admission to hospital she did not look very ill; temperature 100°, pulse 120, respirations 28. The throat was red and covered with loose mucus, but not painful. The abdomen was distended and tender all over, the maximum signs being in the right iliac fossa. No mass was palpable per vaginam, and only moderate tenderness.

In view of the possibility of infection following the miscarriage, and the condition of the throat, expectant treatment was given.

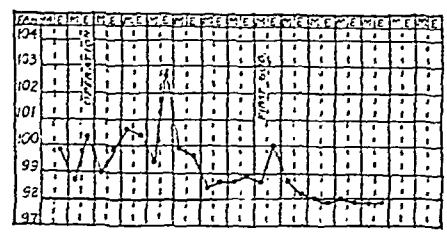
Her condition remained much the same for seven days, except that localization became more definite in the right iliac fossa. Laparotomy now showed: (1) general redness of the whole intestinal tract; (2) copious sero-sanguineous fluid; (3) patches of gelatinous exudate on the bowel and on the surface of the leaves

of the mesentery—evident precursors of mother-of-pearl plaques; (4) an enlarged and acutely inflamed appendix, which was removed.

Operation was followed by prompt clinical recovery, and the patient left hospital on the twelfth day after operation, the throat being normal. The Wassermann reaction was positive.

The appendix was submitted to Dr. W. H. Grace of Chester, to whom we are indebted for the report printed at the end of this communication. The features are well shown in the accompanying photomicrograph.

CASE II.



A woman, aged 26, complained of the sudden onset of right-sided abdominal pain with pyrexia. She was admitted to hospital the following day with a provisional diagnosis of acute appendicitis.

On admission the temperature was 100°, pulse 92, respirations 20. She was pale, but did not look very ill. The tongue was evenly covered with white mucous exudate. The abdomen was distended but not tense; it was tender all over, but moved with respiration. The maximum tenderness was quite definitely in the right iliac region. Nothing was found per vaginam.

The treatment was expectant; the tongue improved a little with mouthwashes.

The condition remained stationary, and on the fourth day of the illness laparotomy showed: (1) intestines peppered all over with small punctate and star-shaped haemorrhages; (2) a small amount of free serous fluid; (3) a large appendix, acutely inflamed and covered with plastic lymph.

On opening the appendix the mucous membrane was found to be of a uniform pale pink with no evident ulceration. The

thickening was clearly due to infiltration of the subperitoneal and submucous layers.

Recovery was uneventful, and the patient was discharged on the twelfth day. The tongue became clear the day following the first injection. The Wassermann reaction was positive.

The two cases had the following corresponding features.

CASE I.	CASE II.
Wassermann reaction +.	Wassermann reaction +.
Specific throat.	Mucous patches on tongue.
Denied infection, but was unmarried at the time of the miscarriage.	Denied infection, but had an illegitimate child seven years previously.
One of 10 healthy children, and no miscarriage in the mother.	One of 5 healthy children and no miscarriage.
Mother's W.R. ++. Sister's W.R. +. (No opportunity for examining other members.)	One brother has definite facies of congenital syphilitic.
No vomiting throughout the illness.	No vomiting.
Macroscopically acute appendix with unbroken mucous membrane.	Macroscopically acute appendix with unbroken mucous membrane.

Dr. Grace's Report.

CASE I.—Subperitoneal layer thickened and packed with lymphocytes. Number of lymphatics also full of lymphocytes. Muscular layer normal. Submucosa enlarged, with several small vessels packed with lymphocytes. Histological character consistent with diagnosis of syphilitic infection.

CASE II.—Chronic inflammation scattered throughout submucosa and underlying layers.* There is a predominance of lymphocytic infiltration, and the findings support a diagnosis of syphilis, but further than this it is not possible to go.

There was no evidence of tubercle in either specimen. Efforts to show up the spirochaete by Levaditi and other silver methods were unsuccessful, but, according to Warthin,[2] this is frequently the case in undoubted syphilis.

ATELECTATIC BRONCHIECTASIS.

BY

A. J. SCOTT PINCHIN, M.D., M.R.C.P.,

PHYSICIAN AND PHYSICIAN IN CHARGE OF CARDIOGRAPHIC DEPARTMENT, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK; PHYSICIAN, WEST LONDON AND HAMPSTEAD GENERAL HOSPITALS;

AND

H. V. MORLOCK, *M.C.*, M.D., M.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF HEART AND LUNGS; ASSISTANT PHYSICIAN, HAMPSTEAD GENERAL AND MILLER GENERAL HOSPITALS.

(*With Special Plate.*)

PERHAPS it is true to say that in no branch of medicine has radiology been more useful as a diagnostic aid than in disease of the chest; nevertheless, though the skiagram may show a condition which is definitely abnormal, yet the abnormality present is not diagnostic of the underlying pathological lesion; and, in order to ascertain the nature of the abnormal shadow, the aid of clinical medicine and pathology must be sought.

Such a radiological abnormality is a triangular shadow which is seen at the base of the lung. The shadow is a rectangular triangle, one side of which rests on the diaphragm, the other along the mediastinum; the hypotenuse runs from the mediastinum to the diaphragm. This shadow may appear on either side of the mediastinum, and when it occurs on the left it may lie within the cardiac shadow, and thus tends to be obscured and may be unrecognized at first.

In 1911 Dieulafoy[1] described the clinical findings in cases of mediastinal effusions; not long afterwards the radiological appearance of this condition was reported as being a shadow similar to the triangular shadow described above. The following case illustrates this.

H. W., aged 11 years. Four weeks before admission to hospital the patient had felt "off colour"; slight cough was present, with occasional traces of sputum. *Physical examination on admission* showed impaired percussion note and absent air entry at the left base behind. Temperature 99.8° on admission. The skiagram showed a triangular shadow behind the heart shadow (see Fig. 1). After a few days in hospital the temperature fell and the patient felt quite well; during the four ensuing weeks the physical signs gradually disappeared. A second skiagram showed that the shadow had gone, and that lipiodol could not demonstrate the presence of any bronchiectasis (see Fig. 2).

One brother of the patient had recently died of pulmonary tuberculosis, and another brother was suspected of the disease. The effusion was probably tuberculous in origin. Wallgreen[2] has described a similar case in which diagnosis was confirmed by exploratory puncture.

Recently the occurrence of massive atelectases of the lung has attracted considerable attention, from both the clinical and radiological sides, particularly the massive atelectases occurring as a post-operative complication, or as a result of haemoptysis; but massive atelectasis may occur in other pulmonary conditions—for example, trauma to the chest wall, pneumonia, and pleurisy. The atelectatic lobe, or part of the lobe, gives a dense shadow on the skiagram, and the mediastinal shadow is displaced towards the side of the lesion. The shadow of the atelectatic lobe may be similar to the triangular shadow now under discussion.

D. S., aged 8 years, came to hospital complaining of a cough which had been present for some time, but which recently had become worse. Physical signs revealed an area of dullness and bronchial breathing at the right base behind. The heart was displaced slightly towards the lesion. The skiagram shows the triangular shadow at the right base with the cardiac shadow drawn towards it. In view of the past history of pneumonia the diagnosis of bronchiectasis was made, and the patient was sent away to a convalescent home. On return the physical signs had disappeared, and lipiodol injection of the lungs showed no bronchiectasis; the shadow had gone from the skiagram and the heart had returned to its normal position.

In the following series of cases the skiagrams of the patients' chest showed the triangular shadow. In their histories these patients admitted to the raising of much sputum, or dated their cough from their recovery from pneumonia; which facts suggest the possibility of a bronchiectasis; the lung was therefore injected with lipiodol, and bronchiectasis was demonstrated within the shadow.

W. A., female, aged 17 years. Had pertussis when she was 4 years old; since then bronchitis, and during the last four years repeated haemoptysis. Patient had been notified as suffering from pulmonary tuberculosis. *Physical signs:* dullness and added sounds at left base. A skiagram showed a triangular shadow behind the heart (see Fig. 3), and lipiodol injection demonstrated bronchiectasis within the shadow.

B. P., aged 11 years, complained of cough which had been present for "years." The amount of sputum raised varied from 1 to 2 ounces. There was a history of patient having had pneumonia at 3, 5, and 10 years of age. Physical signs at left base; dullness, bronchial breathing, and rales. A skiagram showed a triangular shadow behind the cardiac shadow, and lipiodol injection demonstrated bronchiectasis in this shadow.

F. R., aged 14, had suffered from cough for "years." There was very little sputum. Past history of measles. Physical signs were present at the left base, and the fingers showed slight clubbing. A skiagram showed a triangular shadow behind the heart (see Fig. 4); lipiodol demonstrated bronchiectasis within the shadow.

E. S., aged 9 years, complained of cough which had been present since the last attack of pneumonia two years previously. Patient had had pneumonia three times. The sputum raised was offensive and varied from 2 to 3 ounces daily. Physical signs at right base; behind dullness and bronchial breathing, added sounds. Fingers clubbed. A skiagram showed the triangular shadow at the right base. Repeated attempts at lipiodol injection were unsuccessful (see Fig. 5). The facts that the amount of sputum was large and that the physical signs and skiagram remained unchanged for two years leave little doubt that the condition was one of bronchiectasis.

In 1926 Singer and Graham[3] described a case the skiagram of which presented the triangular shadow, and in which bronchiectasis was demonstrated by lipiodol. At operation an atelectatic lung with bronchiectasis was found to correspond to the shadow. Rist, Frocine, and Jacob[4] collected a series of seven such cases, which at first they suspected as being purulent mediastinal effusion, but the lipiodol injection showed the conditions to be bronchiectatic. Wallgreen reported five such cases, and discussed the pathology. He believes that the primary condition in these cases is an atelectasis and bronchiectasis.

It is a matter for speculation how much influence local areas of collapse exert in the etiology of bronchiectasis generally, though it is probable that it may have some bearing in relation to the disease occurring after chronic pneumonic conditions. The clearing up of a collapsed area of lung is dependent on the free mobility of the chest and diaphragm, and occurs least readily in those parts where there is a deficiency of movement.

This condition obtains particularly in that portion of the lung under discussion. Lying as it does in the recess formed by the spine and ribs and the angle of the diaphragm, it is shielded from the more forcible respiratory movements, and is a spot where one would expect to find a residual atelectasis. In such manner we account for the comparative frequency of the condition described: we consider, from the number of cases we have met with, that

* The appearance at operation was anything but chronic.

it is a not uncommon event, and may account for some of those cases of continual attacks of haemoptysis, with no definite signs of tuberculosis or gross disease, which are met with fairly frequently.

In this communication we have called attention to this triangular shadow, and we have discussed its significance; in our experience the most common lesion with which it is associated is bronchiectasis, and we are in agreement with Sergent[5] and Wallgreen that the presence of this shadow should always raise the suspicion of a bronchiectasis unless other clinical evidence is forthcoming to clinch the diagnosis of a mediastinal effusion.

Our best thanks are due to Dr. F. G. Chandler for his kind permission to use the notes and skiagram of the case F. R.

EXPERIENCES WITH REGIONAL ANAESTHESIA.

BASED ON 208 CASES IN WHICH IT HAS BEEN USED.

BY

H. W. L. MOLESWORTH, F.R.C.S.,

ASSISTANT SURGEON, ROYAL VICTORIA HOSPITAL, FOLKESTONE.

IT is probable, if the discovery of novocain had preceded that of cocaine and of chloroform and ether, regional anaesthesia would by this time have been firmly established as the standard method of averting the pain of operations. Events having occurred as they did, regional anaesthesia has had to struggle against adverse conditions, but has steadily gained ground as safer drugs and improved technique have been evolved. One of the chief obstacles to its wider adoption is the entrenched belief that for major operations general anaesthesia is essential. Early fatalities, due to the use of cocaine, or to technical errors in administration, have done the method much harm. Injections of cocaine or of high titres of novocain (1 or 2 per cent.) have been the greatest errors; death has resulted from intravenous and intraspinal injection. According to Finsterer intravenous injection is easily avoided by adherence to two rules: (1) in regions free from large blood vessels[4] injections should be made only with a moving needle point; (2) in dangerous areas it is necessary to aspirate before injection and repeatedly during injection.

The number of cases (208) here dealt with is too few to suggest conclusions about the relative safety of regional and general anaesthesia, but in this series there has been no death directly attributable to the anaesthetic, and one only in which it is possible that the anaesthetic (spinal) played a part. A survey of the series can, however, give some idea of the value of the method to a general surgeon who is prepared to give some time and trouble to the acquisition of a technique which, though not easy, is fascinating.

Drugs and Solution Strengths.

I have tried novocain, borocain, tutocaine, quinine-urea, and eucupin, and though the first three of these have given satisfactory service, I prefer tutocaine, for the reasons presently to be stated.

Novocain (with Adrenaline).—Novocain has a low toxicity. Solutions of 1 in 400 may be used for infiltration anaesthesia; 1 in 200 is adequate for field-block procedures, and 1 per cent., and in rare instances 2 per cent., for blocking the large nerves. The stronger solutions should be used with extreme caution.

Borocain will give similar results; it is said to be superior for producing surface anaesthesia and to be less toxic than novocain. I can state from personal experience that 10 c.cm. of a 2 per cent. solution may produce toxic symptoms in a patient of lowered resistance. Solutions of borocain have the disadvantage that they are extremely sensitive to slight changes in reaction.

Tutocaine is, strength for strength, more toxic than novocain, but it appears to be much quicker in its action, and in 1 in 500 solutions has proved a thoroughly reliable anaesthetic. A 1 in 500 solution of tutocaine appears to be as effective for field block as a 1 in 200 solution of novocain.

Quinine-Urea.—I have not given this drug an extensive trial. Used alone it causes initial pain on injection, and it has a tendency to produce oedema, which persists for some time.

All these solutions are made up with normal saline and are sterilized by boiling; adrenaline is added (the synthetic variety will withstand a few seconds' boiling). The solution becomes pinkish; it may be used so long as the colour is not a mahogany; 1 c.cm. of 1 in 1,000 adrenaline is added to each 250 c.cm. of solution.

Classification of Results.

Many difficulties arise in attempting to assess the results of regional anaesthesia, two of the chief being the following: (1) the patients vary greatly in their reaction to a painful, uncomfortable, or an emotional stimulus; (2) it is difficult to assess the quality of anaesthesia where inhalation anaesthesia has been used in combination with regional anaesthesia. All cases in which it has been intended from the first to combine the two methods are classified in the following table as "intended combined." The quality of anaesthesia is classified as "poor" in

Table showing Results in 208 Cases in which Regional Anaesthesia was Employed.

Operations.	No. of Cases.	Intended Combined.	Quality of Anaesthesia.			Technique.
			Good.	Fair.	Poor.	
Major operations on stomach and gall-bladder	26	2	24	—	—	Anterior splanchnic anaesthesia (Braun).
Ditto	5	1	2	1	1	Posterior splanchnic anaesthesia (Kappis).
Ditto	4	—	2	2	—	Mesenteric anaesthesia (Finsterer).
On abdominal wall ...	15	3	12	—	—	Field block.
Appendicectomy	6	—	4	2	—	Field block and mesenteric (Finsterer).
Hernia: radical cure ...	15	—	14	—	1	Field block.
Jejunostomy and caecostomy	5	—	5	—	—	Field block.
Various abdominal operations	50	1	31	12	6	Spinal anaesthesia.
Suprapubic cystotomy	11	—	11	—	—	Field block.
Perineal prostatectomy...	4	—	4	—	—	Trans-sacral.
Suprapubic prostatectomy	3	—	—	3	—	Field block and epidural.
Operations on testicles ..	2	—	2	—	—	Field block.
Urethrotomy	3	—	3	—	—	Epidural 30 c.cm. 1/5% tutocaine.
Cystoscopy in males ...	15	—	14	—	1	Ditto
Excision of breast ...	3	—	3	—	—	Field block.
Empyema	4	—	1	3	—	Field block.
Thyroidectomy: excision of glands of neck	5	—	5	—	—	Paravertebral cervical block.
Perineorrhaphy: repair of cervix (D. and C.)	4	—	4	—	—	Field block: broad ligament block.
Haemorrhoids	5	—	4	1	—	Field block.
Operations on upper extremity	6	—	4	1	1	Brachial plexus block (Kulenkampff).
Hallux valgus; Mayo's operation	3	—	3	—	—	Field block.
Sympathectomy, femoral	1	—	1	—	—	Field block.
Excision of tongue ...	1	—	1	—	—	Field block.
Operations on foot ...	2	—	—	1	1	Anterior tibial and posterior tibial block.
Saphenous varix	1	—	1	—	—	Field block.
Circumcision	3	—	2	1	—	Field block.
Varicocele	2	—	2	—	—	Field block.
Amputation of penis ...	1	—	1	—	—	Field block.
Hydrocele	2	—	2	—	—	Field block.
Operations on hand ...	1	—	1	—	—	Median and ulnar block.

all cases where the administration of inhalation anaesthesia was not intended but became obligatory; in some of these cases the patient's emotional attitude rather than pain was the cause of failure. Under the heading "fair" are included the cases of patients who preferred to endure discomfort rather than to accept the proffered ether, or of patients who accepted ether anaesthesia too light to abolish consciousness. A preliminary explanatory talk was given to each of the patients, and then, as a routine, each patient received, one hour before operation, and again half an hour before operation, an injection of omnopon 1/6 grain, and scopolamine 1/400 grain.

It will be seen that in 163 of the 208 patients the results were completely satisfactory; in 27 they were adequate; and in 11 they were poor. In 7 cases anaesthesia was "intended combined."

Abdominal Operations.

The outstanding advantage of regional anaesthesia is that it facilitates the more difficult upper abdominal operations by securing an immobile abdominal wall and permitting exact suturing. This advantage is more apparent in cachectic patients, who, under regional anaesthesia, will withstand a severe operation better than they would a palliative operation under general anaesthesia.

For operations involving no traction on the viscera—for example, gastrostomy, repair of ventral hernia, cholecystgastrostomy, gastro-jejunostomy in patients with ptosis, and cholecystostomy—block anaesthesia of the abdominal wall is entirely adequate; for operations such as gastrectomy splanchnic anaesthesia by Braun's method is sufficient, but when for any reason, such as aspiration of blood, the application of Braun's method is impossible, mesenteric anaesthesia is usually adequate. When dense adhesions are anticipated, as in secondary operations on the stomach or biliary tract, the posterior route of Kappis is chosen, but with the precautions suggested by Finsterer—namely, putting the patient in a sitting position and using a weak solution. There is no objection to adding light ether anaesthesia during a difficult stage; but any approach to the state of excitation results in a loss of many of the advantages of regional anaesthesia. I find that the majority of patients decline ether when it is offered to them, or after they have taken a few breaths; but this applies only to patients who have been efficiently injected, and affords evidence that their pain is not very severe. Of 50 patients who had operations on the upper abdomen, 6 were kept under very light ether anaesthesia; 40 of the remainder required no ether, and 3 accepted small inhalations during the stage when traction was severe. In one case only was full ether anaesthesia called for. The method of regional anaesthesia is advocated in upper abdominal surgery because it gives the surgeon greater freedom in choosing appropriate operative measures, offers him certain facilities during operation, and helps to ensure to the patient a smooth convalescence.

Appendicectomy.—The interval appendix and the early acute appendix may be removed with less discomfort to the patient than he would experience if the operation were carried out under ether anaesthesia. The technique of administration described by Finsterer has been used. In certain cases of retrocaecal appendix the patient will require a little ether or gas during the brief stage when the appendix is being separated. In six cases such additional anaesthesia was required twice.

Inguinal and Femoral Hernia.—In these operations regional anaesthesia gives full relaxation, a bloodless field, and absence of post-operative straining; for these reasons it is certainly the method of choice. The one patient in whom it proved inadequate was a nervous man who, through an oversight, did not receive the preliminary sedative; he reacted so violently to a needle puncture that ether was started at once, and the operation was carried out without further injection.

Jejunostomy and Caecostomy.—A patient suffering from intestinal obstruction who needs simple drainage of the intestine may be operated on painlessly and with ease by the field-block procedure.

Genito-urinary Operations.

Suprapubic cystotomy for drainage, more especially in uraemic subjects, may be carried out under regional anaesthesia. If the surgeon wishes to explore the bladder with the finger it is more comfortable for the patient, though not necessary, to add epidural anaesthesia (caudal block) with 1/5 per cent. tutocaine.

Prostatectomy, by either the perineal or suprapubic route, may be carried out with trans-sacral anaesthesia, using 1/5 per cent. novocain. If the suprapubic route is to be used a field block will be needed as well. The administration of trans-sacral anaesthesia is one of the more difficult procedures, but the technique fully repays the trouble taken in acquiring it. Even if the procedure is only partially successful it is surprising how little disturbance the operation of prostatectomy causes the patient.

For cystoscopy in patients who, without anaesthesia, tolerate examination badly, caudal anaesthesia has proved ideal, and operations on the urethra may be carried out by the same method. By using 20 to 40 c.cm. of 1/5 per cent. tutocaine I have had no failures.

Miscellaneous Operative Procedures.

Recently I have been using field block combined with injections into the broad ligaments for operations on the vulva, vagina, and uterus by the vaginal route, with very encouraging results. Relaxation and a bloodless field make a perineorrhaphy by this method much easier.

Anaesthesia of the neck by paravertebral injection has proved completely satisfactory. I use the modified lateral approach to the transverse processes of the cervical vertebrae. In this method, devised by Meeker, the needle approaches from above downwards, and from without inwards, so as to mask the vertebral vessels by the transverse processes.

I have induced brachial plexus block six times. For this purpose 1/5 per cent. tutocaine appears to be too weak, but I have had no failures with 2 per cent. novocain. I have used the method for screwing a fractured olecranon, excision of the elbow, bone graft for radius and ulna, and reduction of fracture. Where 2 per cent. novocain is used extreme care must be taken to avoid intravenous injection.

Spinal Anaesthesia.

I have left spinal anaesthesia to the end because, although it represents the largest single item, I am using it less and less frequently. Experience shows that more reliable procedures are available for upper abdominal surgery. A great drawback of spinal anaesthesia is that one cannot be certain of the level of anaesthesia. In four cases out of fifty in my own series the level was too low. Moreover, in all cases there is a fall of blood pressure which is partially controllable by ephedrine; in six cases, however, the fall was severe, and in two, in spite of ephedrine, it was really alarming; in one of the latter it probably contributed to the death of the patient. I now use spinal anaesthesia in one type of case only—namely, in intestinal obstruction, where, I believe, its risks are outweighed by its advantages.

Conclusion.

Post-operative bronchitis and pneumonia are not eliminated, but it appears to be less common where regional anaesthesia has been used. Patients may vomit once, but the cause is probably post-operative medication and nervousness. Post-operative distension is very rare except in cases of organic obstruction or when the patient is uraemic. Wounds heal as well after regional as after general anaesthesia, except when drugs, such as quinine-urea or eucupin, are added to secure for the patient post-operative freedom from pain or ability to cough; in these circumstances tight suturing produces a small slough. In bronchitic patients this minor defect is compensated by the benefit to the patient of being able to cough freely.

The beginner should not start with the more difficult procedures. Even the technique of injecting the abdominal wall can be acquired only after practice.

A CASE OF ECLAMPSIA TREATED WITH SPINAL ANAESTHESIA.*

BY

R. H. PARAMORE, F.R.C.S.,

RUGBY.

On April 29th, 1929, shortly after 8 p.m., I was called to assist my colleague Dr. Waugh in the treatment of a case of eclampsia. I suggested that the administration of chloroform, if it was not already in progress, should be started at once. On my arrival I found a young, massive woman lying on her side in bed. She was almost fully dressed, was under the influence of chloroform, comatose, and breathing stertorously. The room was dismantled for spring cleaning.

The patient, aged 22, a primigravida seven months pregnant, had been quite well till half-past seven that evening. She had been feeling sick occasionally, but had regarded this symptom as unimportant. At the ante-natal clinic, where she had attended once a month, her condition was considered to be good. She ate a great deal, and was habitually constipated. At seven o'clock she had gone upstairs to help in the spring cleaning of the bedroom where she was lying. She knelt down to clean a chair, and said that she felt sick. She was told to sit down, and was given a glass of water. She took a sip of water and was helped into the bed. No sooner was she on the bed than she had a fit, and as the fit/or fits continued and her condition became alarming, Dr. Waugh, who had never seen the patient before, was sent for. He immediately injected a quarter of a grain of morphine (8.15 p.m.) and sent for me. The administration of chloroform was started at about 8.30.

As soon as I saw the patient I made preparations to induce spinal anaesthesia. To expose the patient's back her combinations were cut, a low corset being removed. With due precautions I made a lumbar puncture, drained off about two drachms of cerebro-spinal fluid, which was apparently under normal pressure, and then slowly injected 1.8 c.cm. of tropacocaine. This ended the treatment. The administration of chloroform was stopped; no vaginal examination was made, and not even a catheter was passed to collect urine.

It was now nearly 9 o'clock; the patient lay still, and her respirations were regular, loud, gurgling, and at the rate of about 24 a minute; the pulse, which previously had been about 72 to 80 in rate and bounding in quality, soon began to quicken and lose its volume; its rate increased to 104, and at times it could scarcely be felt at the wrist. On auscultation of the chest I could clearly hear the signs of fluid in the bronchi, and I thought that pulmonary oedema had occurred. For these reasons the foot of the bed was raised. Shortly before 10 o'clock the clinical picture changed. The patient turned her head, grimaced, and moved her arms as though to wipe her face. Muco-pus which had collected about the mouth and nostrils was wiped away, and the patient settled on her side, apparently in sleep. The breathing was now quiet, and on auscultating the chest I found that respiration was normal and the mucous rales had disappeared.

I left soon after 10 o'clock, but when at 11 o'clock I returned, the nurse, who had arrived during the interval, informed me that the patient had had another, very slight, fit, which had lasted only three minutes, after which she had once more become comatose. I found the patient semi-conscious, but at moments restless and moving about. I gave instructions that she was to be kept on her side; that if the bowels did not move naturally an enema was to be given, with the patient still on her side; and that if she became conscious she was to have nothing but water by the mouth.

The next morning (April 30th) Dr. Waugh and I saw the patient again; she was completely conscious, and had passed a restless night, but no further fit had occurred. She had complained to the nurse of "uterine pain." The night report was as follows:

11.10 p.m.	Temperature 97.4°; pulse 130.
11.40 p.m.	Simple enema given, not retained; patient very restless.
12.30 a.m.	Vomited.
1.0 a.m.	Vomited.
1.40 a.m.	Vomited again.
2.40 a.m.	Regained consciousness; passed urine, 20 ounces.
3.0 a.m.	Temperature 97.2°; pulse 104. Sips of water given.
3.15 a.m.	Soap enema given; very good but very constipated result.
9.0 a.m.	Temperature 98°; pulse 84.

Thus the patient had vomited, had had an action of the bowels, and had passed plenty of urine. The pulse and breathing were normal, and the blood pressure was 110/65. The patient was still a little confused, and had no knowledge of what had happened. On examination we found that the uterus was enlarged to the size of a seven months' pregnancy, and we heard the foetal heart. There had been no vaginal discharge, and a vaginal examination was not made. No urine had been kept for analysis. We allowed the patient nothing but water with sodium bicarbonate, ordered another enema, and forbade visitors.

From that day the patient's condition steadily improved; she had no more fits, and various symptoms, such as backache, headache, and buzzing in the head, gradually disappeared. She was allowed up on May 7th, and on May 15th, when she visited the ante-natal clinic, her condition was found to be good, and the urine, though alkaline, was normal. She had her baby, a male weighing 7½ lb., on June 20th, and Dr. Waugh, who attended, reported that delivery was normal. I saw the patient on June 23rd; she was smiling and well. Her blood pressure was 120/80, and a catheter specimen of urine was normal. It is noteworthy that albumin was found once only (May 1st), and in much smaller amount than was expected. Whether it was present at the time of the attack (April 29th) or the next day cannot be stated. Unfortunately, the child died at the end of a week, but the mother was discharged well on July 3rd.

I wish to express my indebtedness to Dr. Waugh for giving me the opportunity of treating this case.

* Dr. Waugh reported this case briefly in the *British Medical Journal* of October 12th, 1929, p. 663.

THE SIGNIFICANCE OF OXALURIA.

BY

J. V. C. BRAITHWAITE, M.D., M.R.C.P.,

PHYSICIAN, LEICESTER ROYAL INFIRMARY.

In the routine microscopical examination of urinary deposits it is not uncommon to find octahedral crystals of calcium oxalate. Apart from the formation of calculi, this oxaluria is not considered by most modern authorities to be of clinical importance. It is said that the great majority of persons passing even large numbers of individual oxalate crystals suffer no inconvenience. This absence of urinary symptoms is all the more remarkable when we consider the known effects of oxalic acid and soluble oxalates on the kidneys. Numerous workers have reported that these substances, introduced either orally or subcutaneously into animals, produce tubular nephritis, and Shaw Dunn and his co-workers[1] have shown that in rabbits, guinea-pigs, and dogs the intravenous administration of oxalates causes an intense nephritis, which primarily attacks the first convoluted tubules, and which for some months seriously affects the power of the kidney to excrete urea. It is interesting to note that they conclude that the deposition of calcium oxalate in the tubules plays no important part in this process. In man the ingestion of oxalates is sometimes followed by urinary symptoms.

During the past five years four patients suffering from oxalic acid poisoning have been admitted into the Royal Infirmary at Leicester, and in the only fatal case there was suppression of urine. In 1915 three anonymous correspondents in the *Lancet*[2] reported symptoms observed in themselves after taking rhubarb, which were attributed to the oxalic acid in the vegetable. Of these, one had dysuria and blood in the urine, one had dysuria alone, and one had no urinary symptoms.

There is, in fact, a considerable amount of evidence that oxalates in a state of solution are highly toxic to the kidney, and it would appear that the absence of serious symptoms in individuals passing calcium oxalate is dependent on the extreme insolubility of the lime salt. It was formerly believed that calcium oxalate crystals only separated out after the urine had stood for some time, being held in solution by acid sodium phosphate. That this is not the case is shown by the frequent finding of oxalate crystals in freshly passed acid urine, and by the entire absence of impaired renal function in these cases.

Presumably, then, calcium oxalate is sometimes excreted as such by the kidney. It would nevertheless be surprising if these sharp, hard crystals should pass over the delicate renal tissues without causing some disturbance, and that mechanical injury can be caused in this way the following case appears to show.

A boy, aged 15, consulted me on August 1st, 1929, for haematuria. He had been seen eighteen months previously for hilum tuberculosis, but six months' sanatorium treatment had apparently completely cured this condition. The haematuria of which he now complained had had a sudden onset a few days

beforehand; it was profuse and quite painless. He maintained that he felt quite well, and had absolutely no symptoms other than blood in the urine. A thorough examination revealed no abnormal physical signs. The urine was bright red, and a microscopical examination revealed, in addition to large numbers of red blood cells and a very occasional blood cast, the presence of many octahedral "envelope" crystals of a size rather larger than those usually seen in urine. He was put to bed, and given a milk diet with alkalis. On the following day there was much less blood in the urine, but the crystals were even more abundant. On the next day there was neither blood nor albumin in the urine, and only an occasional crystal was seen. The systolic blood pressure was 125 mm. of mercury, the diastolic 70. The blood urea was 23 mg. per 100 c.cm. No tubercle bacilli were found in the urine, and an *x*-ray examination showed no stone in the urinary tract. A week later there was nothing abnormal in the urine, and the boy has remained well since.

This patient had always had a fair amount of rhubarb in the summer, and during the past season had had more than usual. However, none had been taken for a fortnight before the onset of haematuria.

The Nature of the Crystals.

Although these crystals were of the octahedral form typical of calcium oxalate, it was thought advisable to investigate their chemical characteristics. So long ago as 1862 Neubauer and Vogel[3] pointed out that very similar forms could be obtained by crystallizing out sodium chloride from a solution containing urea. Another possible mistake is the confusion of an unusual form of ammonio-phosphate of magnesia with calcium oxalate. A specimen of urine containing the crystals was centrifugalized, the deposit was shaken up in a tubeful of distilled water, and this was again centrifugalized. The process was repeated, and the crystals were found to be still undissolved; therefore they were not sodium chloride. They were then similarly washed in dilute acetic acid, but remained intact, so that they were not triple phosphate. They were, however, soluble in hydrochloric acid, but were recovered from this solution on neutralizing it with lime water. Thus there can be no reasonable doubt that they were truly crystals of oxalate of lime.

It would be foolish to generalize from a single case, but the history of this patient is, I think, suggestive. It suggests, first, that the passage of calcium oxalate crystals is not always as innocuous as supposed, and that some cases of unexplained spontaneous haematuria may be due to a similar cause; secondly, although calcium oxalate can cause some mechanical damage to the kidney, the absence of symptoms, the rapid recovery, the normal blood pressure, and particularly the normal blood urea, of this patient show that it is the safest form in which the body can excrete any abnormal accumulation of oxalates in its substance.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ACUTE APPENDICITIS COMPLICATED WITH PARATYPHOID FEVER.

THE association of the above two diseases seems of sufficient interest to warrant recording.

A healthy-looking adult, aged 22, was admitted to hospital complaining of a sharp bout of pain in the right lower quadrant of the abdomen. His temperature was 100.8° F., and pulse 80 per minute. Tenderness was present over the appendix area and there was some muscular rigidity, more marked on the right side. Tenderness was elicited on the right side when he was examined per rectum. He had vomited once. Acute appendicitis was diagnosed and he was operated upon. The abdomen was opened by a gridiron incision. Some free peritoneal fluid was found. The appendix was long, thick, tortuous, and very much inflamed. It was removed and the wound closed without drainage. The appendix was opened and found to contain blood and pus.

Next day the temperature was 99° and pulse 72. On the second day after operation the temperature and pulse were normal, and the patient felt very well and appeared to be making an uneventful recovery. However, on the third evening after operation the temperature suddenly started rising, and the next morning reached a maximum of 103.2°, while the pulse remained steady at 80. This was accompanied by diarrhoea of a dysenteric type. The stools consisted chiefly of greenish-yellow mucus, with here and there pale yellow "cheesy" masses containing pus cells and also bright red blood clots—about two or three per stool. The stool was examined bacteriologically.

One thought of the possibility of dysentery, or post-operative peritonitis, but the steady pulse, soft abdomen, absence of pain, and the general well-being of the patient were against the latter. That evening he had a sharp bout of epistaxis and later vomited some old blood; this latter was probably the result of the former, because neither epistaxis nor vomiting was repeated. He now complained of a sharp pain in the region of the umbilicus, which was relieved by going to stool. The motions (about six per diem) continued to show the bright red blood. The fever continued but the pulse remained steady. This lasted for six days, the fever gradually diminishing and the general condition of the patient always remaining surprisingly good. In the meantime, from the stool an organism had been isolated, cultured, and identified as *Bacillus paratyphosus* B. The appendix wound healed by first intention, and the patient made a good recovery from the paratyphoid fever.

It may be mentioned that the paratyphoid B is the common form of enteric in this part of Germany, but, as far as the British garrison is concerned, this was an isolated case. Apparently the sudden onset with rapid rise of temperature, dysenteric stool, infection of the colon causing bright red blood clots in the stool, steady pulse, etc., are all compatible with a paratyphoid B infection, but at the time this case caused great difficulty clinically in diagnosis.

The following questions are of interest. When did the paratyphoid fever start, and was the pathological condition of the appendix due entirely to *B. paratyphosus* B? If the condition of the appendix was entirely due to *B. paratyphosus* B, and if it had not been removed, would it have perforated, causing peritonitis? Unfortunately the appendix was not examined very carefully after operation, or sectioned, because it appeared an ordinary routine case. It may be mentioned, however, that at the operation there was no evidence of inflammation in the coils of small intestines seen, or in the commencing portion of the ascending colon, whereas the appendix was acutely inflamed. Finally, was free peritoneal fluid the result of a paratyphoid B infection in the lumen of the intestines?

My thanks are due to Lieut.-Colonel H. St.M. Carter, D.S.O., M.D., O.C. Connaught Hospital, Wiesbaden, for help and advice with the case; to Major J. W. Houston, D.S.O., M.B., for the laboratory work done, and to Lieut.-Colonel E. M. Pennefather, R.A.M.C., for permission to publish the case.

J. F. WILDE,
Lieutenant R.A.M.C.

Wiesbaden.

ACTIVE PULMONARY TUBERCULOSIS OF EXCEPTIONALLY LONG DURATION.

THE following case appears to be of sufficient interest to warrant publication.

X. Y. recently died of pulmonary tuberculosis at the age of 60. He gave a history of having suffered from "bronchitis" since he was 8 years of age. When he was 14 he commenced work as a compositor, but from the commencement he lost a great deal of time owing to cough and malaise, and he was told by his medical attendant that he was "in a decline." At the age of 27 he had an attack of pleurisy, followed by blood-stained sputum, and was definitely diagnosed as suffering from pulmonary tuberculosis. When 39 years of age he was sent to the Brompton Hospital, where he was found to have a cavity in the right lung.

He came under the Hertfordshire County Council Tuberculosis Scheme at the age of 47, and he was found to have signs of widespread disease in both lungs, and tubercle bacilli in the sputum. With an occasional course of sanatorium treatment he was able to continue at his occupation until the age of 53, when he was pensioned off. At no period of his life had he been able to live and work as a fit man, and he never remembered being without cough and sputum. The last two years of his life were spent more or less in bed.

From the above history it would appear that the patient had suffered from active pulmonary tuberculosis which was slowly progressive for forty-five or fifty years. Until the last two years of his life his general condition remained fairly good, but whether the marked chronicity of the disease was due to exceptional resistance of the patient or to an infection of low virulence is a matter of doubt.

A. P. FORD, M.R.C.S., L.R.C.P., D.P.H.,
Tuberculosis Officer, Hertfordshire.

Reports of Societies.

BLACKWATER FEVER.

AT a meeting of the Royal Society of Tropical Medicine and Hygiene on December 12th, 1929, a discussion on blackwater fever opened with a joint paper presented by Professor WARRINGTON YORKE and Drs. F. MURGATROYD and D. UVEDALE OWEN. The paper was confined to a description in very close detail, illustrated by tables and charts, of five cases of blackwater fever occurring in this country which Professor Yorke and his colleagues had had the opportunity of carefully observing from beginning to end, and in connexion with which all the various clinical, biochemical, and serological tests had been applied. Attention was drawn to the dissimilarity of the temperature charts in blackwater fever cases to those in cases of malaria, both malignant and subtertian. As regards the connexion between blackwater fever and malaria, the interesting hypothesis was advanced of binary fission occurring in the ordinary propagation of the malignant tertian parasite. The authors agreed that much interest surrounded the question of the existence of a pre-blackwater state, which, however, they had not been able to distinguish.

Dr. C. M. WENYON suggested that there might be a subliminal condition, in all respects identical with blackwater fever, except that there was no haemoglobinuria.

Dr. FRANCIS CHARLESWORTH thought that blackwater fever was quite distinct in its origin from malarial infection. Although malarial parasites, benign or malignant, had been found in a proportion of cases of this fever, it did not follow that these were the cause, which might be some hitherto undiscovered ultra-microscopical organism. In a part of Zanzibar where he had spent his medical career it was quite easy for a European to contract blackwater fever, but he had never known a case to occur in a native. On the other hand, when some Indian agriculturists were sent to Zanzibar to work on the land, all of them malarial subjects, four died of blackwater fever.

Dr. G. R. ROSS, speaking from experience in Southern Rhodesia, said that there was no doubt that in a certain number of cases of blackwater fever fatigue and chill could not be invoked as exciting causes; twenty-three patients in a series of 180 seen by him personally or notified to him developed blackwater fever while in bed in hospital under treatment for malaria. The part played by quinine in the genesis of an attack was considerable, and he mentioned the case of a patient with malignant tertian malaria who manifested haemoglobinuria within three-quarters of an hour of beginning quinine treatment.

Dr. D. B. BLACKLOCK emphasized the necessity for team work in the elucidation of blackwater fever; it was not a condition which was likely to be elucidated by the efforts of a single person. In connexion with Professor Yorke's suggestion that binary fission might be responsible for the propagation of the malignant tertian parasite in malaria, he mentioned observations which went to show, in persons dying from malaria, that the internal organs, especially the spleen, had a great number of sporulating forms in comparison with those in the peripheral blood.

Dr. P. H. MANSON-BAHR mentioned a case of sudden onset of blackwater fever in a hospital patient with tertian malaria who had been on carefully graduated quinine treatment for ten days. It was rare to get blackwater fever developing in people with large numbers of subtertian parasites in the peripheral blood. Even when there was blockage of the capillaries of the brain, the peripheral blood might still show very few subtertian parasites. He had been struck by the large, soft, and painful spleen in people who were about to develop blackwater fever; whereas it was rare to find a painful spleen in an ordinary attack of subtertian malaria. This organ shrank with great rapidity as the haemolysis cleared up, and there was some clinical evidence for supposing that the primary seat of the haemolysis was the spleen. The last four cases of blackwater fever at the Hospital for Tropical Diseases had been treated by blood transfusion as soon as the blackwater condition commenced, and the clinical results had been excellent, better than anything he had seen before. The introduction of fresh red blood corpuscles put a stop to the haemolytic process.

Dr. N. H. FAIRLEY suggested that detailed investigations of a limited series of cases were likely to produce scientific results of much greater value than the collection of wider statistical data under conditions in which accuracy, and detailed biochemical, serological, and other methods, were impossible. Some work at the Hospital for Tropical Diseases showed that all grades of transition occurred in blackwater fever—from severe to transient haemoglobinuria, and from frank jaundice to no jaundice at all. Recently he had seen two patients transfused during the haemolytic stage, with very dramatic and beneficial results. The haemolysis terminated and the haemoglobinuria cleared up, especially in one of the cases, at an earlier time than could have been anticipated on ordinary treatment. He could not personally support the view that the introduction of foreign blood terminated the haemolytic process, but the fact had certainly been established that it did not increase the haemolysis. Patients with blackwater fever died from one of three causes—namely, the rapid haemolytic process, heart failure, or renal complications—and he thought that transfusion during the haemolytic period was certainly a therapeutic aid of considerable importance.

Dr. H. S. STANNUS suggested that a change in the physical condition of the blood occurred in blackwater fever; this afforded an explanation of the action of quinine and sodium bicarbonate in those cases in which chill or fatigue had been concerned. In Africa cases were seen in which there was definite history of fatigue and chill. Dr. D. THOMSON doubted the division of malarial parasites by binary fission; he had never seen a malarial parasite so divided, and he had performed many successful cultures in malignant tertian fever. Dr. FREDERICK MURGATROYD said that alkalis were beneficial in the treatment of blackwater fever. Dr. D. U. OWEN had been impressed by the fact that the spleen punctures did not contain any more parasites than the peripheral blood.

Dr. G. CARMICHAEL LOW (from the chair) said that blackwater fever was an extraordinary disease in its epidemiology as well as in other respects. India, with the exception of two areas, had none, whereas it was found generally in African countries. The condition was also an extraordinary disease from the point of view that the clinician might have a run of successes followed by an equal run of failures. When Dr. Low went out to Uganda he was met by a distinguished man in tropical medicine who assured him that the only treatment for blackwater fever was quinine in large doses. On replying that they had been taught at the School of Tropical Medicine on no account to give quinine, he was referred to a list of recent cases in which unvarying success had followed this treatment; but, unfortunately, of the very next six cases so treated, every one died.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of the Liverpool Medical Institution, held on November 28th, 1929, Miss FRANCES IVENS described the scheme for a national maternity service drawn up by the Medical Women's Federation, of which a full summary appears in the *Supplement* to this issue (p. 5).

In the course of the discussion which followed, Dr. LEITH MURRAY said that in its broad features the scheme conformed to the recommendations of the British Medical Association and the report of the Departmental Committee on the Training and Employment of Midwives. He considered that to increase the status of midwives was a necessity, but would prove a difficult and probably a costly problem. Only by subsidy and superannuation would it be possible to get a better class of candidate—namely, the generally trained nurse—to undertake the duties and drudgery of the profession of midwife. He emphasized the importance of ante-natal examination, and insisted that any attempt to carry out the more serious part of such work by one not qualified by special experience was bound to lead to the very difficulties which any national maternity service was designed to avoid.

Mrs. BARTON HALL said that it was mainly from the laboratory point of view that she was interested. Until recent years laboratory services had been looked upon as

somewhat of a luxury, but nowadays we were accustomed to rely on the State for a limited amount of laboratory service, and this was provided for in the scheme outlined by Miss Ivens.

Dr. C. O. STALLYBRASS stated that in Denmark maternity assistance was included in the insurance scheme which provided for the medical care of wives and children of insured persons, and in that country maternal mortality was exceptionally low. The capacity of the midwife had greatly improved since the passing of the Midwives Act; the statistics of cases confined under the care of the Queen Victoria District Nurses were exceptionally favourable in relation to both morbidity and mortality. It was his opinion that great practical difficulty would be experienced in enforcing a quota number on practising midwives.

Miss R. NICHOLSON considered that an important point in the scheme was the position of the general practitioner who was to be consulted by the expectant mother before she engaged her midwife. This would prevent selection of the doctor by the midwife, and booking by her of unsuitable cases.

Dr. ARTHUR GEMMELL said that he would like to hear the views of general practitioners, as he felt that some form of national maternity service would shortly be forced upon the profession. It would be most helpful if practitioners could give their views as to what would be possible, and what would be reasonable in the way of fees, as thirty shillings per confinement appeared to him to be much too small. He also feared that the introduction of such a service would lessen the number of patients available for teaching students, and thought that possibly some arrangement might be made whereby selected doctors and midwives could keep in close touch with teaching maternity hospitals and notify these institutions when they had labours in progress which students could attend.

Dr. H. H. MACWILLIAM said that in his opinion Liverpool women were more and more inclined to have their confinements conducted in hospital rather than in their own homes. There was already a shortage of maternity beds in the Poor Law hospitals, and more accommodation would have to be provided before long. He thought a maternity scheme based on insurance with friendly societies would not be easy to work, and that the friendly society part of the National Health Insurance Scheme had not been a complete success.

Dr. H. CANTRELL remarked that the £250 income limit included many women who do not at present attend a clinic or hospital out-patient department, but engaged their own medical attendant for their confinement. Many of these women would prefer to have their doctor present at a normal confinement at their own expense, and she suggested that they should be allowed to do so even whilst taking advantage of the other benefits of the scheme. Dr. Cantrell was glad to see that provision of sterile dressings was included in the scheme, and suggested that the sterilization of sheets would be even more ideal.

Professor BRIGGS spoke about his forty years' experience of midwifery in Liverpool, and Miss IVENS, in her reply, acknowledged the great work Professor Briggs had done to improve the teaching of obstetrics in that district.

DIABETES MELLITUS.

A MEETING of the Pathological Society of Manchester was held on December 11th, 1929. Professor SHAW DUNN, opening a discussion on diabetes mellitus, described the sugar metabolism in the body and the part played by insulin. He reviewed the experimental work on animals, and grouped the pathological changes in human beings under the following headings: (1) cirrhotic changes between the acini; (2) hyaline thickening of the fibrous septa of the islets and degeneration of the islet cells (occurring in cases of old-standing disease); and (3) hydropic degeneration of the islet cells. In many severe cases no evidence of the disease could be found in the pancreas. Dr. T. H. OLIVER classified the disease into three types: the pancreatic, defective sugar storage, and the endocrine form. The first type occurred in young people and should be treated with insulin. The second type comprised the majority of cases, and these generally yielded to dietetic treatment or insulin. Probably in a few cases in this group there was also a lesion in the liver, such as haemochromatosis; in these patients the prognosis was serious because insulin had no effect. In the third type the ductless glands were at fault; diabetics with exophthalmic goitre died rapidly even with insulin. The speaker reported cases showing the intermittency of symptoms sometimes due to a seasonal variation, for the relapses often occurred at the same season in which the patient was first affected. There was sometimes a strong family history, often associated with instability of the ductless glands. He attributed child diabetes to infection, instancing the case of diabetes following mumps. The indications for insulin were: (1) extreme youth, (2) bad family history, (3) complications such as gangrene, carbuncles, or phthisis, and (4) onset of a yellow coloration of the skin. Attacks of hypoglycaemia might come on very rapidly, and sometimes took the form of epileptiform attacks, transient hemiplegia, or mental disturbances. Diabetic coma had nothing to do with sugar, and the blood sugar was no guide to its onset; acetone was a guide, but was not the cause, and it was probable that protein was the determining factor. When albuminuria appeared coma was at hand, and, if untreated, a flood of fatty casts usually appeared in the urine and the patient died of uraemia with suppression of urine. Dr. LANGLEY agreed that diabetes was often infectious in origin; he had had two cases following broncho-pneumonia. He described cases of transient diabetes of suprarenal, cerebral, and alimentary causation.

FREE PERFORATIVE DIVERTICULITIS.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, with the president, Mr. R. ATKINSON STONEY, in the chair, Sir WILLIAM WHEELER described the clinical course of a fatal case of diverticulitis, which perforated into the free peritoneal cavity. A full account of the case is printed at page 5.

The PRESIDENT referred to the fact that the caecum had been brought out through the main incision, and suggested that, if a separate opening had been made on the opposite side, the caecum might have drained itself, and prevented the high obstruction. Mr. A. CHANCE said that he was inclined to think that the vomiting was not mechanical but toxic, and wondered if the whole condition could have been toxic. Mr. H. STOKES said he would like it made more clear that there really was a diverticulum in this case. He had come across many cases of perforation of the large intestine, but without diverticula. He drew attention to the fact that it was fatal to insert tubes into dilated gut with the object of draining. Mr. F. J. HENRY said that free perforative diverticulitis was a great rarity. He had seen only one case, in a woman who, two years previously, had been operated on for carcinoma of the breast. There was no difficulty in closing the perforation, and the patient recovered fairly easily.

Sir WILLIAM WHEELER replied that the caecum was loose, and it was possible to perform caecostomy through the primary incision. With regard to Mr. Chance's question, he believed that the obstruction which followed septic peritonitis was usually mechanical; loose adhesions between loops were the cause of obstruction. He referred to a paper by Dr. Charles Mayo on this subject. Mr. Stokes had asked if the diagnosis was certain. The loop of bowel was removed after death, and the perforation of one of many diverticula demonstrated.

Principles of Radium Therapy.

Dr. OLIVER CHANCE, who read a paper entitled "Some experiences in an English radium clinic," illustrated by numerous lantern slides, said that if radium was to be used effectively it was necessary to possess a thorough knowledge of the principles upon which treatment was based. The most important factor in the response of a tumour to radium was its histology. Examples which served to illustrate this fact were to be found in the different results which followed irradiation of carcinoma of cervix uteri and rectum, and, again, the better response to radium of growths on the posterior third of the tongue than those on the anterior two-thirds. An adequate dose and a homogeneous dose must be given. The condition of the surrounding tissues influenced the action of radium. The cavitation procedure should never be used if any other

method was practicable. Implantation was the best treatment in certain regions. Wherever possible, needles should be used in preference to seeds, since it was difficult to secure a homogeneous irradiation with the latter. Surface irradiation was applied through moulds of various sorts. Distance irradiation was theoretically the best method, but it was wasteful and expensive. Dr. Chance described the various techniques employed in different regions, and indicated the results of treatment. He said that it was just as difficult to assess the results of radium in treating cancer as to decide the value of salvarsan in the treatment of syphilis. Time and the keeping of careful statistics alone could help. He added that all that could be said at present was that radium was the best means for dealing with a limited group of cancers, and that with the passing of time, and the increasing knowledge which it would bring, this group might be enlarged.

Dr. W. C. STEVENSON said that a number of cases which were seen by him were quite incurable, and palliative treatment alone was possible, but he thought that this was very well worth while. He seldom saw cases of cancer of the tongue without extensive glandular involvement; much better results could be obtained if the glands were unaffected. In carcinoma of the cervix he found it difficult to give three treatments, since patients, especially those from the country, would not return, so he tried to do as much as possible in one session. He asked Dr. Chance how he ensured that the threads in the needle escaped being cut, since, if this happened, radium might be lost. Dr. R. STUMPF, referring to radium and to deep x-ray therapy, said he thought it was impossible to say that one method was superior to the other. In carcinoma of the cervix the results obtained from radium and from deep x rays were much the same, but in mammary cancer, if the tumour was large, he preferred deep x-ray therapy. Dr. M. R. J. HAYES said that it was absolutely necessary to know the histological nature of the growth in order that the dose might be properly regulated, and also to be able to give some idea as to the prognosis. Enlarged submaxillary glands were often inflammatory, and there was a risk of necrosis of the jaw unless care was taken in inserting the needles. In mammary carcinoma, when the whole pectoral muscle had been removed, it was rather difficult to treat patients with radium, unless great care was taken. Dr. R. R. WOODS asked if Dr. Chance thought there was any danger of necrosis of the great vessels of the neck from the proximity of radium needles.

Dr. CHANCE, replying, said that they had to reject about 30 per cent. of the cases that came to them for treatment, because they had not a sufficient supply of radium. The tip was carefully screwed into the needle, so it was impossible for any radium to escape; thread was not used, but fairly stout silk. He thought there was a great future for combined deep x-ray and radium therapy. They did not treat cases of cancer of the œsophagus, since on physical grounds they did not consider the treatment was sound. Some cases of cancer of the larynx did well, while others did badly. In mammary cancer, once nodules appeared, carcinomatosis very often followed. He had never seen necrosis of the great cervical vessels from the proximity of needles.

AT a meeting of the Optical Society, at the Imperial College of Science and Technology, on December 12th, 1929, with the president, Mr. F. TWYMAN, F.R.S., in the chair, Mr. CLIFFORD BROWN demonstrated an apparatus for the Duochrome sight test, which was intended as a substitute for the Snellen chart. The subject compared two lines of black type on red and green illuminated grounds, and the sight-tester added + or − lenses in the trial frame till both lines were equally distinct, when the correcting lens for the *mean ray could* be described. Similarly sets of radiating lines of black on red and green illuminated grounds enabled the axes of an astigmatic eye to be determined, after which the correcting power of each meridian could be found. Mr. S. ADAMS, for C. W. Dixey and Sons, described and showed four types of the Maddox cheiroscope for use in the treatment of squinter's acquired amblyopia, and for the improvement of the correlation between hand and eye.

Reviews.

GARRISON'S "HISTORY OF MEDICINE."

THE subject of medical history is one of the most recent departments in the healing art to receive systematic attention and study. It is now taught in some sixty-three academic institutions, and in Germany, which was one of the first countries to recognize the educational value of this subject, there are some fifteen chairs dealing with the history of medicine. In America, where it has been taken up with great enthusiasm, some nine chairs have already been established. For the intensive study of the subject one of the most remarkable developments has been the establishment of an institute and library of the history of medicine, intended to make possible the whole-time study of history by graduate students under the guidance of a great teacher in the Johns Hopkins University, Baltimore, Professor William H. Welch. This is somewhat on the lines of the Institut für Geschichte der Medizin, which was established in 1905 at Leipzig under the direction of Professor Karl Sudhoff by the widow of the late Professor Theodor Puschmann, an earlier medical historian.

The general textbook which has come to be regarded as the starting-point for study at these and other medical historical centres is undoubtedly Fielding Garrison's *Introduction to the History of Medicine*, of which a fourth edition,[1] revised and enlarged, has now been issued. An interesting preliminary chapter has been added to the book on prehistoric phases, from which it appears that early man must have been peculiarly liable to disease, for, among the few well-known remnants that have been discovered, it is stated by the author:

"The femur of the Javanese Pithecanthropus shows marked exostoses; the skull of Piltdown man (*Eoanthropus*) signs of acromegaly or of osteitis deformans. The left ulna of the original Neanderthal skeleton is fractured and, in the opinion of Virchow, the left humerus is rachitic. The spine of Heidelberg man (7000 B.C.) shows signs of Pott's disease, which is also common in later Egyptian mummies. Human paleopathology thus goes back to the late Pleiocene (500,000 B.C.), while osteomyelitis in fossil reptiles is already found in the topmost strata of the Paleozoic, which the physician-geologist Murchison called Permian.

"Bacteria probably functioned from the earliest times as rock-builders, by deposition of lime extracted from sea-water. In the Cambrian coal-beds they began to swarm, in the Permian they became pathogenic. . . . Pathogenic parasitism was evolved from easy-going commensalism and symbiosis in the Cambrian period. In course of time 'familiarity bred contempt and advantage-taking.' Worms began to bore into crinoids, even as the sponge justifies its name by boring into the oyster. Osteomyelitis and caries began to attack the reptiles, armored amphibians, and fishes of the Permian. The oldest known fractures occur in Permian reptiles of Texas. The earliest known bony tumour (*hemangioma*) was found in a Mesozoic dinosaur of Wyoming. A crocodile of the Oxford Jurassic shows necrosis with metastases. The aquatic mosasaurs and plesiosaurs of the Kansan Cretaceous show osteoperiostitis, osteoma, arthritides, and dental caries; a fracture of the humerus in a horned dinosaur resulted in a subperiosteal abscess with several liters of pus."

Notice is taken of the Edwin Smith medical papyrus, dating from 1600 B.C., and recently described by Breasted, which consists of a roll over fifteen feet long of cursive script, dealing with forty-eight cases in clinical surgery; in some of these cases feeble pulse and fever are noted in hopeless head injuries; in dislocation of the cervical vertebrae paralyses of the arms, legs, and sphincters are noted as unfavourable symptoms. This defective copy appears to be the remnant of some great surgical treatise which had long ante-dated the surgical works of Hippocrates. An interesting account is given of the mediaeval period of medicine, when, as Colonel Garrison says, the heresy imposed by the Arabic commentators of Galen that coction or suppuration was essential to the healing of wounds, made operative surgery a perilous and meddlesome undertaking, when the surgeon, too, whether scholar or mountebank, stood in danger of life or limb if he operated unsuccessfully on any of the feudal lords. To this period, however, belonged Theodoric, Bishop of Cervia, who about

[1] *An Introduction to the History of Medicine.* By Fielding H. Garrison, A.B., M.D. Fourth edition, revised and enlarged. Philadelphia and London: W. B. Saunders Company. 1929. (6 × 9¼, pp. 996; illustrated. 55s. net.)

1266 contradicted the dogma of coction and stood out as a sturdy pioneer of a simple expectant dry treatment, or rational asepsis; William Salicet, professor at Bologna about 1268, whose book on surgery contains the first known treatise on surgical anatomy; Lanfranc of Milan, who introduced the reunion of divided nerves and recommended neurotomy for tetanus; and Henri de Mondeville, who, in 1306, recommended the aseptic treatment of wounds by simple washing, since "wounds dry much better before suppuration than after it."

In the latter part of the book an effort has been made to do justice to the recent medicine of Russia, Italy, Spain, and the Latin American countries. Sections deal with modern sectarians and quackery, the development of modern medical periodicals, the tendency towards internationalism in medicine, and the special advances in medicine and surgery which originated in connexion with the world war. The author believes that "it is in Russia that the great future problems of social medicine will be tried out on a grand scale." Connected with the Peoples Commissariat of Public Health (1918) are institutes of protozoan disease, of communicable diseases, for control of serums, of physiological nutrition, of hygiene, of biochemistry, of tuberculosis, etc., but it is pointed out that of 33,000 physicians some 29,500 are virtually chattels of the State, at salaries of twenty to sixty-five dollars monthly, most of the doctors being "country shy" on account of the dreary isolation of the rural districts and the vast distances to be travelled in the course of practice. A valuable set of appendices, which have been to a large extent rewritten for the present edition, include one on the chronology of medicine and public hygiene, extending to over seventy pages of small type, and including most of the events in medical history from prehistoric times up to 1928; hints on the study of medical history, which form a useful guide to the methods adopted by various teachers; some forty pages of bibliographic notes, which give references to monographs dealing with various medical subjects, and particularly to important figures in medical practice; and, finally, a series of suggestive questions and exercises, which have been rewritten for the present edition, and which may form a serviceable guide for students.

The work is interesting, concise, and reliable as ever, and it forms a valuable companion alike for the teacher and the student of medical history, whether it be for the purpose of consecutive reading or for occasional reference.

PATHOLOGY AND TREATMENT OF DIABETES.

IN the preface to his work on the physiopathology and treatment of diabetes mellitus,[2] Professor LEGUEU refers to the admirable qualifications of M. Chabanier, as chief of the chemical laboratory at the Necker Clinic, to investigate the biochemical problems which diabetes presents. The book under review comprises the results of laboratory and clinical experiences collected and collated by M. CHABANIER and his two collaborators, Dr. LOBO-ONELL and Mlle LEBERT. For some years M. Chabanier has been convinced of the important part which the kidney plays in determining the clinical course of diabetes, even though the initial disturbance of the glyco-regulation may be due to pancreatic disease. Following the classification of Marcel Labbé, Chabanier makes a substantial distinction between diabetes with wasting and diabetes without wasting. Great stress is laid on the essential mobility of the renal threshold for glucose, and many examples are given of the threshold varying or remaining constant under alterations of the blood sugar level. It is shown conclusively how frequently the glycaemia and glycosuria do not run parallel. The first part of the book, devoted mainly to the chemical problems of the diabetic state, is long and intricate, but it well repays careful attention, for much of the work has not been published before. The second half deals with the treatment of diabetes and its complications. The authors' experiences with insulin lead to the noteworthy conclusion, "au lieu de restreindre systématiquement la ration en hydrates de carbone suivant la tendance de cette époque nous proposions, au contraire, de donner la quantité la moins restreinte possible de ces substances, telle cependant, dans chaque case particulier, qu'elle n'entrave pas l'instauration par l'insuline d'un état aussi voisin que possible de la normale." Not only do the authors consider that an adequate ration of carbohydrate diminishes the risk of insulin hypoglycaemia, but they regard it as the best and quickest way of restoring the general health. There is a curious observation about insulin hypoglycaemia—namely, that hypoglycaemia is more liable to occur in proportion as the preparation of insulin is more completely purified. But in this connexion we notice that the authors seem to inject the dose of insulin invarably just before the meal. They do not appear to have explored the varying effects of allowing a longer or shorter time to elapse between the administration of insulin and the meal, variations which are purely individual and influence the insulin effect most profoundly. Taken as a whole this is a delightful and stimulating treatise on diabetes.

In *Diabetics*[3] Dr. LUND presents for the guidance of diabetic patients instruction upon the essential points of the disease, the management of diets, and, what is almost equally important, their personal hygiene. The author is to be congratulated on his excellent summary of hints on hygiene. For his diet rules we have less admiration because, when he sets out a scale of gradually increasing diets, No. 15 reaches a total of 2,779 calories, and yet only contains 92 grams of carbohydrate as compared with 231 grams of fat (which, in the light of modern teaching, is an unnecessary stinting of carbohydates), and because of his predilection for brown bread over white. It is true he does not disregard (on page 22) the need for warning the reader that the brown or wholemeal bread must be of an unsweetened variety, but he does not emphasize the fact that the ordinary brown bread is frequently kept moist by the addition of molasses. Perhaps this book, sound as it is in its general tenor, serves to demonstrate our fear of carbohydates in the treatment of diabetes with the aid of insulin, even in despite of Dr. Banting.

Only a year has passed since the appearance of the fourth edition of Dr. LAWRENCE's book *The Diabetic Life*,[4] but in the fifth edition, just published, the author has incorporated a large number of new recipes for diabetics and of detailed examples of line diets. In this edition, moreover, he has made full use of the analyses of the carbohydrate content of foods, carried out by himself and Dr. R. A. McCance, and published last year in a Special Report (No. 135) of the Medical Research Council (*British Medical Journal*, July 27th, 1929, p. 156). From these analyses it appeared that there was much less available carbohydrate in most vegetables and fruits than had been supposed, and the food values now given differ appreciably, therefore, from those in the previous editions.

PRICE'S "MEDICINE."

THE appearance of a new edition of *A Textbook of the Practice of Medicine*,[5] by various authors, marks a definite event in the London school of medicine, and the editor, Dr. F. W. PRICE, is to be complimented on successfully guiding his large team for a third time. A great deal of the book has been revised and rewritten, and various changes have been made in the classification and arrangement. Rickets, for example, after wandering into the diseases of metabolism in the second edition, now comes back to the section on deficiency disorders. The list of new articles and new matter is a long one, and it is only possible to pick out a few items for comment. The section on metabolic disorders opens with a very good account of basal metabolism, and Dr. R. H. A. Plimmer has contributed an excellent article on vitamins. In Dr. Price's own contribution on the heart he has added a short article on cardiac infarction, and among other additions and alterations is a very

[2] *Physiopathologie et Traitement du Diabète Sucré.* Par H. Chabanier, M. Lebert, et C. Lobo-Onell. Préface du Professeur Legueu. Paris: Masson et Cie. 1929. (Roy. 8vo, pp. 444. Price 50 fr.)

[3] *Diabetics.* By John Knowles Lund, M.R.C.S.Eng., L.R.C.P.Lond., D.P.H.Manch. London: The Scientific Press, Faber and Faber, Ltd. 1929. (Fcap. 8vo, pp. 87; illustrated. 3s. 6d. net.)

[4] *The Diabetic Life.* By R. D. Lawrence, M.D., M.R.C.P.Lond. Fifth edition. London: J. and A. Churchill. 1930. (5½ × 8½, pp. viii + 204; 10 figures. 8s. 6d.)

[5] *A Textbook of the Practice of Medicine.* By various authors. Edited by Frederick W. Price, M.D., F.R.S.Ed. Third edition. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (5½ × 8, pp. xxxviii + 1871; 115 figures. 36s. net.)

good account of syphilitic affections of the aorta, heart, and pericardium. In the rearrangement of this section it is a pity that the description of angina pectoris has not been brought nearer to that on coronary disease.

In the section on diseases of the kidneys a brief note on nephrosis has been included, together with an account of the hyperpietic kidney. The description of uraemia has now been placed after nephritis, but, following Dr. Izod Bennett's recent lectures and book on the subject, this disorder requires a different method of approach to be up to date, and no mention is made of the acute haemorrhagic type of nephritis, which is certainly the commonest form in childhood. Dr. Hugh Thursfield has revised his contributions on purpura and on Gaucher's splenomegaly. In the former he gives a good critical summary of the modern views on the relation of the platelets and of splenectomy to the different varieties of purpura, and in the latter a short but complete account of this disorder, now looked upon as an inborn error of metabolism. The section on glandular fever has been largely rewritten, and the account of the medico-legal aspects of tests for drunkenness has been revised. A good description of Schilder's encephalitis is now included in the section on diseases of the nervous system, which remains one of the best parts of the whole book.

The new matter and the alterations in arrangement have added only about fifty pages to the total length of the volume, which, though it contains nearly 2,000 pages, remains remarkably compact in size. Unfortunately this compactness has been attained by the use of such thin paper that the type on the reverse side of each page in the copy submitted for review shows through sufficiently to make reading unpleasant. For the rest, this edition is worthy of its predecessors, and, generally speaking, each of the twenty-six authors has presented an impartial account of his subject, with just enough of the personal touch to make each section distinctive. The whole production is certainly worthy of the traditions of London medicine.

PRACTICAL PHYSIOLOGY FOR MEDICAL STUDENTS.

PHYSIOLOGY is fortunate in having a number of admirable textbooks designed for the service of medical students. Prominent among those which have found favour over a number of years are two practical class manuals, of which new editions have recently made their appearance. The senior book is HALLIBURTON'S *Essentials of Chemical Physiology*.[4] The other is *Practical Physiology*,[5] by Professor E. P. CATHCART, the late Professor NOËL PATON, and Professor M. S. PEMBREY. In both cases the new editions are significant by reason of changes in authorship.

The name of Professor Halliburton has been associated with *Essentials of Chemical Physiology* for thirty-six years, during which time eleven editions have been published. Professor Halliburton has now, however, been constrained to relinquish the full burden of authorship, and has called to his assistance Dr. J. A. HEWITT and Dr. W. ROBSON, whose names consequently appear upon the title-page. The result has naturally been a revision of the text more extensive than might otherwise have been the case. At the same time the general scheme of the book remains unchanged. A good deal of new matter has been introduced to bring some sections up to prevailing standards of medical education. The additions have, on the whole, been wisely conceived and ably executed, and the book has lost none of its authority. Of the new material that dealing with the applications of physical chemistry is the least convincing. The student is, for example, asked to mix equal volumes of decinormal acid and alkali, and to determine the *p*H of the *mixture*. The result of such an experiment in the hands of an elementary student would almost certainly be most misleading. We note an error in the *p*H attributed to decinormal sodium hydroxide; the value given is fourteen: it should be thirteen. Speaking generally, this remains the best brief textbook that we know of introducing the medical student to the minimum requirement in theoretical and practical biochemistry.

Practical Physiology has also suffered a change in authorship in its third edition through the death of Professor Noël Paton. The whole burden of revision has, consequently, fallen upon the shoulders of Professors Cathcart and Pembrey. The book is an excellent practical manual, to which each author has contributed his distinctive share. Emphasis is, throughout, placed upon the practical application of physiology to medicine, and the experimental work is so designed that as much of it as possible may be carried out upon man as the subject. The section entitled "Physiological histology" is of particular interest as a comment upon the increasing tendency for the teaching of histology to pass from the physiologist to the anatomist. The purpose of this section is to emphasize continually the functional significance of the structures which the student observes under the microscope. The section on chemical physiology covers the usual field, but does so with a lucidity and authority which is not so easy of attainment. The author has mitigated the difficulty of his task by a rather optimistic assumption of the extent of the student's knowledge of organic chemistry. We must again take exception to the unsatisfactory treatment of the subject of hydrogen-ion concentration. Authors must face the fact that few medical students have had an opportunity of understanding the theoretical basis of "*p*H," and they should attempt to meet the defect more adequately, otherwise it were better to leave the subject alone.

PREVENTIVE MEDICINE IN CHILDHOOD.

A VERY good introduction to the study of preventive medicine in the period of childhood has appeared entitled Social Hygiene for Infants and Young Children,[3] by Dr. EUGEN STRANSKY, who is an assistant in the State institution for the care of mothers and infants in Vienna. In an introduction, the director of the institution, Professor LEOPOLD MOLL, points out that the latest advances in hygiene are often buried in textbooks and periodicals where the general practitioner is unlikely to find practical advice in the confusion of pro and con arguments. This booklet, of a little over a hundred pages, represents an endeavour to give the doctor the advice he needs in order to apply the latest advances to his patients. The three parts deal respectively with the newly born, the infant, and the young child, and in each case the author sets out first the causes of mortality and morbidity at the different age periods and the way in which these causes can be dealt with and the statistical rates improved. Such disorders as intracranial haemorrhage in the newly born are well described from the preventive point of view, and in the second and third parts the prophylaxis of tuberculosis is clearly set out in light of recent work such as that of Calmette and his *B.C.G.* vaccine. The various acute infectious fevers are dealt with and details are given about the application of the Schick and Dick tests and the production of active immunity, while there is a very good account of "hospitalization" and its dangers for children of different ages.

NOTES ON BOOKS.

THE fifth edition of *Recent Advances in Medicine*,[2] by Dr. G. E. BEAUMONT and Professor E. C. DODDS, appears little more than a year after the fourth, and, without being materially increased in size, it has been brought up to date throughout. This has been effected by omitting certain sections—a wise plan, because some of the material in the first edition can no longer justifiably be called recent. Among the new matter is an excellent section on nephritis, which gives a very good clinical classification of the various types and correlates them with the biochemical findings. To complete this section the authors might perhaps devote space in the next edition to

[4] *The Essentials of Chemical Physiology*. By W. D. Halliburton, M.D., LL.D., F.R.S., J. A. Hewitt, Ph.D., D.Sc., and W. Robson, Ph.D., D.Sc. Twelfth edition. London and New York: Longmans, Green and Co. 1929. (Demy 8vo, pp. xi + 383; 55 figures. 9s.)

[5] *Practical Physiology*. By E. P. Cathcart, M.D., D.Sc., F.R.S., D. Noël Paton, M.D., LL.D., F.R.S., and M. S. Pembrey, M.D., F.R.S. Third edition. London: E. Arnold and Co. 1929. (Demy 8vo, pp. xvi + 573, 256 figures. 18s. net.)

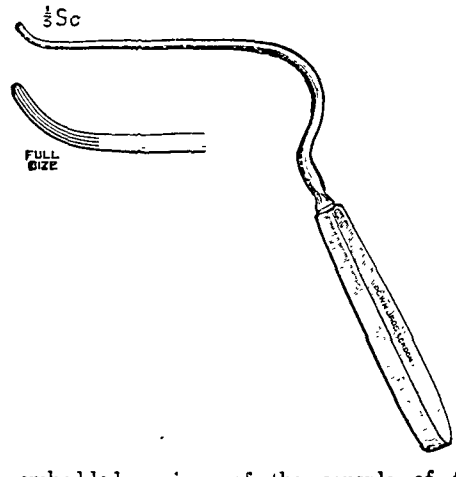
[3] *Sozialhygiene im Säuglings- und Kleinkindesalter*. Von Eugen Stransky. Mit einem Vorwort von Hofrat Professor Dr. Leopold Moll. Leipzig und Wien: F. Deuticke. 1929. (Sup. roy. 8vo, pp. vi + 129; 6 figures. M.8.)

[2] *Recent Advances in Medicine*. By G. E. Beaumont, M.A., D.M.Oxon., F.R.C.P., D.P.H.Lond., and E. C. Dodds, M.D., Ph.D., B.Sc., M.R.C.P.Lond. Fifth edition. London: J. and A. Churchill. 1929. (8½ x 5½, pp. xiv + 442; 53 figures. 12s. 6d.)

the theories of the causation of uraemia. The section on diabetes and diabetic coma is fully up to date, and the account of the latter is one of the best of its kind in modern medical literature. The fifty pages on methods of blood and urine analysis have been carefully revised in the light of recent work. With this edition "Beaumont and Dodds" will undoubtedly continue the popularity it has justly won.

Mr. ERIC A. CROOK has managed to condense a great deal of the information to be found in the large manuals—such as Whitman's or Jones and Lovett's *Orthopaedic Surgery*—into the 228 diminutive pages of his book[10] in the Students' Aids Series. Its appearance is a sign of the great importance which orthopaedic surgery has attained in the present century. In such a small work it is not possible to give more than the essential facts, but we may hope that by it the reader will be stimulated to seek for more in larger works, and, better still, in orthopaedic clinics. Ultimately skill in orthopaedics can be acquired only by observation and practice. It may be easy to describe the manipulations necessary for the reduction of a congenital dislocation of the hip, but it is only by seeing and feeling and trying for himself that the surgeon can learn to carry out these manipulations successfully. The work contains few illustrations, but they are better than none; there are necessarily no reproductions of radiograms, which are of such importance and so illuminating to the orthopaedic surgeon.

If the claims of the authors, Messrs. SORRIN and MILLER, be well founded, the publication of *The Practice of Periodontia*[11] should prove a landmark in the history of "pyorrhoea." By the use of sodium sulphide the epithelium of the pockets is destroyed, and by pressing the raw connective tissue surface against the roots of the teeth, already scaled and cleaned, till clotting blood has formed a bond of union, an opportunity is given for fresh cementum and periodontal attachment to form, and later for new alveolar bone to be built up round the teeth. Besides the usual scaling and cleaning, the preliminary measures include treatment of "traumatic occlusion." To this the authors devote considerable attention, but we cannot gather what it is nor how it acts. Nor are the *x*-ray pictures purporting to show regeneration of bone very convincing. The claim, however, is made by men who are obviously thorough in their work and have a wide experience, and should lead others to put it to the test. The experience of the authors leads them to assert that elimination of pyorrhoea often cures eye troubles, rheumatism, sciatica, constipation, etc.

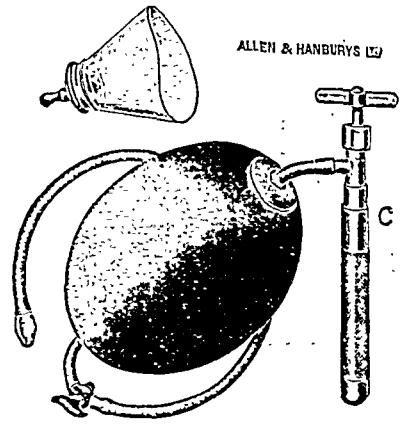


[10] *Aids to Orthopaedic Surgery.* By Eric A. Crook, M.Ch.Oxon., F.R.C.S.Eng. Students' Aids Series. London: Baillière, Tindall and Cox. 1929. (Pott 8vo, pp. viii + 232; 17 figures. 3s. 6d. net.)

[11] *The Practice of Periodontia.* By Sidney Sorrin, D.D.S., and Samuel Charles Miller, D.D.S. New York: The Macmillan Company; London: Macmillan and Co., Ltd. (Post 8vo, pp. xv + 160; 122 figures. 15s. net.)

PREPARATIONS AND APPLIANCES.

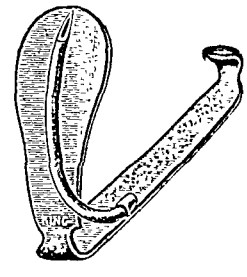
A TONSIL PRESSOR.



MR. HERBERT TILLEY, F.R.C.S., writes: It is a common experience to find that a healthy-looking tonsil contains septic material in the depths of its crypts, and that this can only be made to exude on the surface of the tonsil by pressure on

the outer, embedded regions of the capsule of the gland. Messrs. Down Bros. have made for me this very convenient instrument which enables such pressure to be applied without obstructing the view of the surgeon. If some cotton-wool be wound tightly round the curved terminal of the instrument, considerable pressure may be exerted without damaging the overlying mucous membrane or causing much discomfort to the patient.

PORTABLE OXYGEN INHALING APPARATUS.



Dr. L. S. T. BURRELL (physician to the Brompton Hospital and the Royal Free Hospital) writes: Patients who find relief from oxygen inhalations have complained of the inconvenience

of the large oxygen cylinder when they are travelling. In order to meet with this difficulty, Messrs. Allen and Hanburys Ltd. (Wigmore Street, London, W.1) have made for me a small portable apparatus, which is depicted in the accompanying illustration.

A TONGUE BLADE FOR ANAESTHESIA.

Dr. V. EADES VESSELL (anaesthetist, Royal Northern Hospital) writes: When introducing the Boyle-Davis gag, trouble is frequently experienced in manipulating the tongue into correct position. The accompanying tongue blade has been designed to overcome this difficulty. In addition, the anaesthetic tube is carried to the end of the blade, instead of terminating half-way, as is customary, thus giving a true endo-pharyngeal anaesthesia, and the supply of anaesthetic or oxygen is not impeded by swabbing or haemorrhage. The terminal portion of the blade, being more sharply curved than usual, draws the base of the tongue forwards. This blade has been made to my design by Messrs. A. Charles King, Ltd., 34, Devonshire Street, W.

DANGEROUS DRUGS REGULATIONS.

Appointment of Dental Tribunals.

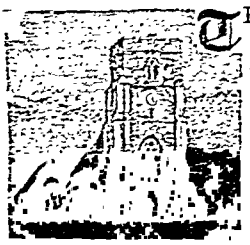
THE Home Secretary gives notice that, in pursuance of the Dangerous Drugs (Consolidation) Regulations, 1928, he has appointed two dental tribunals—one for England and Wales and one for Scotland—to which, as occasion arises, may be referred for examination and consideration any case in which there is, in his opinion, reason to think that a dentist may be administering any of the drugs to which the Regulations apply, either to himself or to any other person, otherwise than as required for purposes of dental treatment.

The appointment of the tribunal is an extension to dentists of the system already adopted with regard to medical practitioners on the recommendation of the Departmental Committee on Morphine and Heroin Addiction in paras. 65-75 of its report issued in January, 1926.

England and Wales.

Mr. W. H. Dolamore, M.R.C.S., L.D.S. (Chairman), nominated by the Dental Board of the United Kingdom; Mr. E. C. Sprawson, *M.C.*, M.R.C.S., L.R.C.P., L.D.S., nominated by the General Medical Council; and Mr. N. G. Bennett, M.B., B.Ch., M.R.C.S., L.R.C.P., L.D.S., nominated by the British Dental Association, or Mr. F. Butterfield, nominated by the Incorporated Dental Association; with Mr. E. Percival Clarke, K.C., as legal assessor.

Scotland.



Mr. W. Guy, F.R.C.S., L.D.S. (Chairman), nominated by the Dental Board of the United Kingdom; Mr. J. H. Gibbs, F.R.C.S.Ed., L.R.F.P.S. L.D.S., nominated by the General Medical Council; and Mr. W. Graham Campbell, M.B., C.M., L.D.S., nominated by the British Dental Association, or Mr. G. Hogg Patterson, nominated by the Incorporated Dental Association; with Mr. John Cowan, K.C., as legal assessor.

THE MEMORIAL TO WILLIAM HARVEY.

BY

SIR JOHN ROSE BRADFORD, K.C.M.G., M.D., F.R.S.,

PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS.

HEMPSTEAD CHURCH BEFORE 1832.

THE appeal that will very shortly be issued, and of which a preliminary announcement was made in the columns of the *British Medical Journal* of December 7th, 1929 (p. 1072), will give the medical profession a unique opportunity of providing a suitable memorial of a striking character to one of the greatest of men.

The medical profession is obviously peculiarly qualified to appreciate the magnitude of Harvey's work, because Harvey not only laid the foundations of medicine as a science, and indicated with the utmost clearness the path that should be followed by his successors if real progress was to be made, but he accomplished much more than this owing to his wide range of vision and the far-reaching character of his work. It may be truly asserted that Harvey's method not only marked the birth of physiology, but that it was, and still is, largely responsible for the progress and development of the biological sciences as a whole. Harvey's method and discoveries were what are spoken of as fundamental, and the method of Harvey is in daily use by all investigators at the present time, whatever their special aims may be. The fundamental nature of his method and discoveries makes his work much more readily appreciable by those who study the natural sciences than by the world at large; and hence the great public, although they may recognize that Harvey discovered the circulation of the blood, can scarcely be expected to realize the true magnitude and quality of his patient and unremitting investigations. It is perhaps peculiarly fitting, therefore, that those who know—that is, the medical profession—should rebuild a tower that will be visible to all. It may be that in years to come the tower of this ancient church of Hempstead, in Essex, will be known as the Harvey Tower, and this tower will not only commemorate Harvey and his work, but it will also be a token of the esteem and admiration with which Harvey's work is regarded by those best qualified to judge its real value.

Some worthy memorials of Harvey are in existence—several notable portraits, a statue, etc. From these we get some information as to the man himself; but the present proposal is for something somewhat different. It is rather that a great profession should try to express in a suitable form its sense of the greatness of Harvey. Surely a tower to the memory of William Harvey, in the church in which his mortal remains lie entombed in the Harvey Chapel, must commend itself to many as singularly appropriate.

The success of such an appeal as that of the Harvey Memorial Committee will be assured if individual members of our profession will take a personal interest in furthering the scheme, and realize that the occasion is exceptional, in that the collapse and ruin of this church tower has given the medical profession the opportunity of providing a lasting memorial not unworthy of the great man and of the profession of medicine, to which he was so greatly attached.

Donations towards the rebuilding of Hempstead Church tower should be made payable to the Harvey Memorial Fund, and may be sent to Dr. Arnold Stott (58, Harley Street, W.1), who is acting as joint honorary secretary with the Vicar of Hempstead.

A HOSPITAL SURVEY OF GREAT BRITAIN.

GROWING STRENGTH OF THE VOLUNTARY PRINCIPLE.

THAT "Whitaker" of the hospital world, *The Voluntary Hospitals of Great Britain*,[1] appears for the tenth year with numerous tables and analyses showing the position in England and Wales (outside London) and in Scotland in 1928. So effective is the survey that out of a total of 792 voluntary hospitals information has been secured from 759, representing a total of just upon 50,000 available beds. A really wonderful position is disclosed with regard to finance, especially when the fact is taken into account that continued heavy taxation must necessarily to some extent restrain benevolence, and, moreover, that hospitals have to meet increasing demands owing to the progress of medical knowledge and the introduction of new methods of treatment. The sum of £9,604,541 was raised during the year, and £8,199,844 was expended on maintenance and development, leaving a larger credit balance than in any of the previous four years for which figures are given. The totals would be more impressive if the figures for London—the domain of King Edward's Hospital Fund—were included. This is provincial achievement.

Services rendered by Hospitals.

The services which these hospitals rendered to the public are indicated in the simplest way by the statement that the new in-patients during the year numbered 775,425, and the new out-patients over three million, a figure which should be multiplied by at least three to give the total of attendances. This is above the average annual increase. In 616 hospitals the number of surgical operations performed under a general anæsthetic during the year was 582,310. Only 118 institutions give details of the work of their *x*-ray departments, but in these the number of radiographs taken was 416,130, the number of screen examinations was 33,477, and 93,940 *x*-ray treatments were given. In 100 hospitals giving particulars of their massage work, the total number of treatments during the year was 1,064,583. The statistics for the 14 hospitals in England and Wales (again excluding London) associated with medical schools are separately shown. The number of available beds in these is 5,152, the average number occupied daily is 4,631: new in-patients total to 97,814, an increase of 12,500 on the figure for 1924: out-patients number 635,500, an increase of 90,000 over the same period, and surgical operations 103,699.

Hospital Income and Expenditure Dissected.

Dissected figures are more instructive than these big resounding totals. In 661 hospitals which furnish complete returns the income per available bed was £150, and the expenditure £130. The following table compares the sources of income for maintenance of hospitals per bed in England and Wales and in Scotland, calculated to the nearest pound.

	England and Wales.	Scotland.
	£	£
Subscriptions	16	18
Donations, entertainments, etc.	21	12
Workmen's contributions and contributory schemes	39	22
Congregational collections ...	4	3
Patients' payments	29	10
Public services	9	6
Interest from investments ...	19	31
Other receipts	1	2
Extraordinary income	19	23

[1] Published by the Central Bureau of Hospital Information, under the auspices of the British Hospitals Association and the Joint Council of the Order of St. John and the British Red Cross Society. Price 1s. net; 1s. 5d. post free.

Co-operation between the voluntary hospitals and public authorities appears, from the increase in money received, to be most marked in respect to infant welfare, where the total sum has doubled since 1924, and to school children, where it has increased by one-third. The income received from public services is highest under the heading of national health insurance; venereal diseases comes next, and after this, infant welfare and maternity work, and tuberculosis schemes. Patients' contributions are a steadily rising figure, from £17 per available bed in 1924, to £20 in 1928. Workmen's contributions (including the Hospital Saturday Fund) have also risen during the same period from £34 to £39. Subscriptions have fallen slightly, but testamentary benevolence shows a remarkable increase in England and Wales, though not in Scotland. The amount received by legacy has risen by rapid stages from £576,337 in 1924 to £954,463 in 1928.

The expenditure of hospitals per available bed is shown in the following table:

	England and Wales.	Scotland.
	£	£
Provisions	27	27
Surgery and dispensary	17	14
Domestic	24	21
Salaries and wages	44	41

Hospitals and their Medical Staffs.

Appendices to the review contain the results of various inquiries into hospital administration. One inquiry was made as to any restrictions imposed upon former resident medical officers against practice in the locality on the termination of their appointment. Of 52 hospitals replying, 44 had no such restrictive clause nor contemplated any; one was considering the matter, and seven had restrictions against practice, the radius from the hospital varying from two to ten miles, and the period from six months to five years. Particulars have also been obtained as to the position of the resident medical and surgical staffs in representative hospitals having from 150 to 250 available beds. Of the 23 hospitals giving such particulars, 13 appoint resident officers to posts of rather greater responsibility than the ordinary "house man," and generally for rather longer periods. Practice with regard to operative work varies within very wide limits.

Another matter for detailed inquiry has been the question of payment to honorary medical staffs out of contributory funds. The 244 hospitals in England and Wales which replied showed the following position:

Size of hospital.	No payment.	Payment.
100 and more beds	79	6
30 to 99 beds	81	3
Under 30 beds	63	12

None of the 14 hospitals in Scotland receiving income from this source and replying to the questions made any payment. It appears that, generally speaking, the contributions to the newer and definite contributory schemes are higher than those made in the older organized workmen's collections. It is a common practice in cottage hospitals for medical officers to charge fees to the patients. Some of the schemes are intended only to cover cost of maintenance when in hospital, and the practice of payment by the patient to the doctor of fees for treatment is recognized. Again, several hospitals which are staffed by general practitioners in the area who are also insurance practitioners infer that the doctors have already been paid for their services as insurance practitioners, owing to the majority of the patients being insured persons. Hospitals where no payment is made at present out of contributory funds to the honorary medical staff were asked for an expression of local opinion, medical and lay. The answers given are various, but on the whole the "noes" have it, both on the lay and medical side. Here and there, it is stated, such a scheme is viewed with favour by the younger members of the medical staff.

One other matter of topical interest is brought out in this compilation. Motor accidents in 1928 necessitated additional hospital expenditure to the amount of £250,000, a bare tenth of which was recovered either directly or from compensation money. That indefensible anomaly, we may hope, will soon be redressed.

A HISTORIC FOREIGN BODY.

IN the electorate of Brandenburg the succession to the throne had for some time been doubtful; and a pity this was, for never before had the succession been so important. The ruler's father, Kurfürst Friedrich Wilhelm, the great elector, had raised the State to a position it had never attained before. "He found Brandenburg annihilated, and he left Brandenburg sound and flourishing; a great country, or already on the way towards greatness"[1]; and now the new elector is struggling "very hard, if not very wisely, to make his existence beautiful—to make it magnificent at least, and regardless of expense."[2] He was "crooked-backed, with his back half-broken." "The Nurse, in one of those headlong journeys which his Father and Mother were always making, let the poor child fall or jerk backward; and spoiled him much, and indeed was thought to have killed him, by that piece of inattention."[3] He is now filling his court with "*Kammerjunker, Kammerherrn*, Goldsticks, Silversticks, and the other solemn histrionic functionaries,"[4] and later is to achieve kingship as Friedrich I, and "the old electorate of Brandenburg is to become the kingdom of Prussia."[5]

And to all this the succession depended upon one small boy. As Kur-Prinz the elector had married a princess of Hessen-Cassel, who did not live long. "That poor young wife, when dying, exacted a promise from Prince Friedrich that he would not wed again, but be content with the daughter she had left him; which promise, if ever seriously given, could not be kept," and "Prince Friedrich brought his Sophie Charlotte home about fifteen months after"[6]—whence the name Charlottenburg. She gave birth to a son who died, and then to another, Friedrich Wilhelm, who in the year 1692 is a sturdy child of 4, with all the hopes of the head of the house centred on him, no other son having followed. True, the elector has half-brothers, but these he did not want to succeed, for he had never got on with his stepmother the electress Dorothee—whence Dorotheen-strasse. Suddenly one day there is great commotion in the palace—the Kur-Prinz has swallowed his shoe-buckle. But Carlyle must tell the story.

"At a very early stage, he, one morning while the nurses were dressing him, took to investigating one of his shoe-buckles; would, in spite of remonstrances, slobber it about in his mouth; and at length swallowed it down—beyond mistake; and the whole world cannot get it up! Whereupon, wild wail of nurses; and his 'Mother came screaming,' poor mother:—it is the same small shoe-buckle which is still shown, with a ticket and date to it, '31 December 1692,' in the Berlin *Kunstkammer*; for it turned out harmless, after all the screaming; and a few grains of rhubarb restored it safely to the light of day; henceforth a thrice-memorable shoe-buckle."[7]

And there it still is shown, no longer in a Kunstkammer, but in the Hohenzollern museum at the Château of Monbijon, in Room 35, in which are the table and chairs and old clay pipes of the Tobacco Parliament (Tabacs Collegium) from Wusterhausen. It has no longer the date

on the ticket, but a label saying it is the buckle swallowed by Friedrich Wilhelm I in his fifth year—a small silver buckle without sharp points, quite harmless to any child of 4 once it has passed the larynx and is not interfered with except by "a few grains of rhubarb." It is about one inch long with the prong well protected by lying against the loop, and at the other end a round knob wherewith to fix it to the strap—a very ordinary buckle, but had it not passed the larynx no Frederick the Great might have been begotten and the history of Europe would have been changed.

CLINICAL ASPECTS OF PAIN.

To the practitioner of medicine pain presents itself in a very practical fashion; it creates a situation which demands attention and will not brook delay. Neither the doctor nor the victim, at least for the moment, is interested in speculations about the protective value of pain or about the part it has played in the evolution of the race; and, equally, disquisitions dealing with the benefit of pain as an instrument of moral discipline or with its philosophical meaning are, at such times, mere impertinent and even irritating irrelevancies. Upon all these aspects of pain much has been said and written from the comfortable shelter of the easy chair. Yet when put to the question by toothache not even a philosopher can endure it patiently. Relief is the demand of the sufferer, not dissertations, and to this demand the doctor must needs apply himself, although in doing so he has to remember a wider claim. For, of course, behind pain is a cause, and it may well be that to detect and to remove this cause is the only abiding method of securing relief. In short, pain as a clinical event asks both for diagnostic interpretation and for a scheme of effective treatment. The patient naturally insists on alleviation or deliverance, but, while giving this cry the consideration which it merits, the doctor cannot forget that pain may be an outward expression of serious mischiefs which it is for him to discover, and if possible to avert.

It is with a full recognition of these practical ends that Professor Edwin Bramwell, in a lecture printed in our present issue at page 1, discusses pain as a form of disturbance which has to be judged and to be treated by the physician. His long and special experience enables him to speak on the basis of first-hand knowledge and personal observation, and it is appropriate, in view of his family and academic tradition, that he should address his colleagues from the clinical platform. The subject, be it admitted, does not allow either clear-cut definitions or rigid classifications, nor is it one for which a short and certain guide to diagnostic and therapeutic success can readily be constructed. Yet pain as a fact has to be met at the bedside, and thus it is important that those who have given special thought to the issues which it raises should make what contribution they can to the common stock.

When, as frequently happens, pain is associated with physical evidences of disease, there is little difficulty, at least on the plane of practical affairs. Discussion on the nervous structures and pathways involved is a possible exercise, but it concerns, at least in the first place, the physiological classroom rather than the bedside. A symptom which may mean disease, and a physical fact which must mean disease, form a combination that leaves little room for hesitation either in opinion or in action. Somewhat less decisive, though often convincing enough, are pains which in degree and in distribution follow well-recognized traditional lines—as, for example, the pains of angina pectoris and of renal colic. In these the pain may well have features which justify both diagnosis and treatment without any support from physical examination. There is a substantial body of clinical experience to justify this position, though this is not to say that the individual picture is always well defined or that it is invariably a genuine one. It is when pain is neither accompanied by physical signs of organic change, nor marked by characters which compel its identification, that the greatest diagnostic difficulty arises, and to this group of cases Professor Bramwell pays special attention.

On the threshold is the question, Is the pain a real experience, or is it simulated by the patient? The doubt often arises when a claim for compensation is in issue; and while, on the one hand, it is a serious matter to charge a plaintiff with malingering, on the other it is unpleasant to be duped. A negative clinical examination carries much value, and negative skiagrams go to strengthen the conclusion. Do they, however, even in combination, close the debate? Room for dealing diplomatically with this question may be found in a recent discussion at the Medical Society of London, and reported in our issue of December 21st, 1929 (p. 1157). Here is convincing evidence that after violence applied to the skull apparent and satisfactory recovery may be followed by such symptoms as headache, vertigo, and minor mental disturbances, while through the whole story physical signs are entirely absent. The damage, whatever it may be, has been there throughout; it allows convalescence, though causing disturbance later; and it cannot be found on examination. How difficult it is to affirm, in view of such experiences, that negative results to clinical tests prove that the patient's complainings are without justification! If this is true of violence affecting the brain, a similar development may at least be suggested in relation to the spinal cord (the "railway spine" of a former day), and the pain in the back which has multiplied under the Workmen's Compensation Act becomes more and more difficult to label confidently as unreal and assumed. While, however, such problems arise in relation to technical medical evidence, the detection of the malingerer is, after all, not seriously affected. For though this depends negatively on the absence of physical signs of injury, it depends positively on evidence convicting the patient of falsehood or exaggeration or inconsistency. The medical practitioner may well chance upon such evidence, although more commonly the pretence is detected when the malingerer is off his guard and is watched unknown to himself. In brief, the wilfully assumed pain, though hard to denounce on strictly medical grounds, ought not to escape shrewd and careful observation.

From the pain which is "pretended" to the pain which is "imagined" may seem to be a change of name without a change of substance. Nevertheless the distinction is drawn, and not without justification. Indeed, the establishment of it is part of a movement which asserts that the clinical picture of a patient is incomplete if it includes only a bald record of his illnesses and a statement of physical facts as these are observed by the physician. The whole man must be surveyed and estimated, and this not merely as a physiological apparatus, but also as a unit having an individual psychological quality and significance. Many studies are emphasizing this aspect of clinical medicine, and are attempting to systematize and to extend what in some fashion has doubtless been followed empirically and within limits by many practitioners who have been psychologists without knowing it. Among the consequences of this development is a recognition of the possibility of "psychogenic" pain, and the name may be welcome alike to practitioner and to patient. Professor Bramwell has

contributed to this enlargement in the range of clinical observation, and his present quotations from his own case-records can be studied with interest and advantage. They enforce two lessons. The first is that in a very difficult group of cases all is not said when physical examination yields no positive result; and the second, that the practitioner who would be effective in dealing with these patients must cultivate the capacity to estimate the quality of the individual, as well as to gauge the integrity of the anatomical machinery. Pain apart from organic disease may be a very real experience, and the ways of meeting this situation ought to be part of the practitioner's therapeutic equipment. Help to this end will be found in Professor Bramwell's lecture.

THE CANCER PROBLEM IN 1929.

How much nearer has 1929 brought us to a solution of the problems of cancer? It may well be that many who ask this question would derive but small satisfaction from a correct answer—even if it were possible to find one. Anxiety breeds impatience, and to impatient people a year is a very long time. Life is short, says the public; but art is long, add those who are engaged in the scientific study of disease. In cancer research a year's duration may be said to vary; time may gallop, or it may dawdle. During the past twelve months it appears to have trotted steadily forward.

Perhaps the chief contribution in 1929 to the treatment and study of cancer has been the creation of the National Radium Fund, and the subsequent establishment of the National Radium Trust and the National Radium Commission. Leading to these events there had been an intensive propaganda for increasing the nation's radium supply; and, among the leading authorities on cancer, a general agreement had been reached that the public had been denied a valuable form of treatment because the available supplies of radium were insufficient for the country's needs. Side by side with this reasoned propaganda was conducted a less laudable campaign, in the course of which the extravagant and unjustifiable claim was made that the time had already come for the complete supersession of excisional surgery by radium therapy. Fortunately, the balanced statements issued by the Radium Commission, and the notes of warning sounded from time to time by responsible leaders of the medical profession, in our own columns and elsewhere, have done much to quell, though perhaps not wholly to end, this campaign, which, as we have had to remark more than once during the year, has cruelly misled the public and done a great disservice to the cause of radiotherapy itself. With the radium distributed by the National Radium Commission we may hope that in the course of the next few years effective studies of both the scope and the limitations of radium therapy will be carried out in this country. So far radium has been used with most success in cancer of the uterus, rectum, bowel, breast, tongue, buccal cavity, and the skin. In the near future we may expect technical advances whereby radium will be used more effectively in the treatment of cancer of these sites, and that its application may be extended to malignant growths which up to now have been inaccessible to radium therapy. Already the National Radium Trust has placed orders for large amounts of radium, and the Commission has formulated far-reaching plans for distributing radium to those hospitals and institutions which it believes are in a position to put it to the best use. The Commission has decided to recognize as national radium centres only institutions possessing medical schools with complete clinical courses and facilities for instructing students and graduates in the principles and practice of radiotherapy. But for the benefit of hospitals and other institutions to which otherwise it could give no direct aid, it has installed a radon plant at the National Physical Laboratory so that, under proper safeguards, it may supply them with radium emanation.

Under the auspices of the British Empire Cancer Campaign investigations have been continued into the best methods of constructing and using the radium "bomb," by means of which rays from a large mass of radium, suitably screened, can be brought to bear upon malignant growths from a distance outside the body. Hitherto radium teletherapy has been but little used in this country, but with the radium bought by the National Radium Trustees it is proposed to construct several such bombs and to ascertain how they can be adapted to give the best therapeutic results, combined with the greatest economy. Towards the end of the year the Radium Commission handed over one such bomb to the authorities of Westminster Hospital, and treatment with it has already begun. The great disadvantage of radium teletherapy is that the bomb can be applied to only three patients during the time that the same amount of radium in needle form could be applied to one hundred. In the interests of economy, therefore, it will be important to use no more radium bombs than are absolutely necessary, and here it is worth noting that in the treatment of highly radio-sensitive growths (for example, lymphosarcoma and other rapidly growing tumours) teletherapy with hard x rays may be as effective as treatment by the radium bomb, or even more effective. In some cases x rays alone may cause complete disappearance of a malignant growth, in others a combination of x rays and radium may give better results than either of these devices alone. Some measure of success has already been achieved by employing the combined method in the treatment of cancer of the cervix, radium being applied to the local growth and x rays to the gland areas. In treating cancer at this site x rays alone have proved insufficient, a tendency to recurrence having been observed in the primary lesion. During the year the so-called stimulation effect of small and repeated doses of x rays has been studied in animals, but so far it has not been possible to verify the hypothesis that under-dosage quickens rather than retards the growth.

It is too early yet to assess the value of the work on cancer that has been done during the year under the auspices of the Medical Research Council, the Imperial Cancer Research Fund, the British Empire Cancer Campaign, the Manchester, Leeds, and other local cancer committees—to mention but a few of the organizations engaged in cancer research. The war on malignant disease is being waged along a wide front; dramatic advances are few; and perhaps the most substantial inroads into the enemy territory will be made by summation of small advances. Here and there, however, it would almost seem as though a key position has been captured, as, for example, by the Manchester Committee, which, while studying the part played in the production of malignant growths by the lubricating oils used in cotton mills, has obtained information about the carcinogenetic power of various oils and the concentration within them of a cancer-producing principle. In the course of this research two pure compounds of known chemical

composition have been proved capable of producing tumours, and a study has been made of the factors which change a non-carcinogenic into an active carcinogenic substance. Already some of the methods employed for destroying the cancer-producing power of certain oils have proved to be effective, at least in part, and one method led to the preparation of a purified oil which, when subjected to vigorous tests, has failed altogether to produce cancerous growths. Representatives of the cotton industry, after comparing this oil with the crude untreated oil, have said that its lubricating power is unimpaired, and the Manchester Committee is therefore able to hold out the hope that before long it may be possible to put on the market an oil which fulfils the needs of industry without being a source of danger to the workers. Experiments during the year under the auspices of the British Empire Cancer Campaign have afforded evidence of the existence of antibodies having a special toxicity to cancer cells. So far, however, vaccine treatment, while it has brought about the disappearance of certain transplantable tumours, has not been so effective in the treatment of spontaneous cancer.

A striking development during 1929 has been the growth of team work in cancer research. For example, at the reconstructed Mount Vernon Hospital at Northwood in Middlesex, which is now devoted to the study of malignant diseases and their treatment, the clinical and laboratory staffs work together as a team, and the admission of patients is regulated solely according to the needs of the hospital as a centre of investigation. Perhaps the greatest mass attack that has ever been made on the problem of cancer, however, was organized during the latter part of the year, when the Council of the British Medical Association instituted an inquiry, in which all the members of the Association were invited to take part, into the incidence of cancer and its history after treatment. This collective inquiry, which is now proceeding, is limited to cancer of the breast, rectum, cervix, and tongue, and its aim is to gather information about the previous history of patients, the evolution of the disease itself, the nature and results of whatever treatment is undertaken, and the duration of the disease, both when treated and when untreated. These are matters about which the general practitioner is better fitted to supply reliable information than anyone else; but we do not pretend that the ultimate solution of the problems of cancer will necessarily come from him, any more than it will from the surgeon, the physicist, the biochemist, the pathologist, or the radiologist. The need of the moment is for the closest co-operation between all these workers, and if we may venture on a prophecy we would suggest that the near future will see the formation of more and more teams comprising representatives of all these groups, who will together tackle problems which none of them may ever hope to solve separately.

THE TRAFFIC IN DANGEROUS DRUGS.

Public attention has been directed of late to the traffic in dangerous drugs and the efforts to secure its international control from many different points of view. The Women's International League, on November 13th, 1929, devoted a whole day to conferences on the subject, at which the problem was discussed from the Indian, Chinese, and Egyptian aspects, as well as from that of the League of Nations. At the Medico-Legal Society, on November 28th, Mr. Llewellyn Jones, M.P., contributed a paper which recited the labours of the International Opium Conferences at the Hague in 1911–12 and Geneva in 1924–25, the conventions issuing from these conferences, and the legislation based thereon in this country, known as the Dangerous Drugs Acts, 1920–25. In some quarters it has been argued that the appalling excess of production of dangerous drugs over any legitimate requirement is only likely to be remedied by making their manufacture a Government monopoly, a view that is apparently held by Viscount Cecil, Professor Noel Baker, M.P., and Mr. L. A. Lyall, president of the Central Opium Board of the League of Nations. It is at least arguable whether the experience of Government monopolies in India, Singapore, and Hong-Kong has been uniformly successful in reducing the consumption of opium, while the revenue derived from such commerce is not without its bearing on a policy of restriction or suppression. Mr. Lyall recently called attention to the fact that in the Straits Settlements, where one-third of the revenue is derived from opium, "the vast majority of opium smokers learned to smoke opium by buying it from a Government that had given a solemn international pledge to suppress opium smoking." The president of the Central Opium Board of the League of Nations regrets the "whittling down" of the provisions of the Hague Convention of 1912 in regard to smoking opium by the more recent Geneva Convention of 1925. It is good to know that the president of the Board is convinced that "there is only one way to stop the illicit traffic, and that is to stop the surplus of drugs that is being produced throughout the world," a conclusion and a policy that have been consistently set forth for more than a decade by this *Journal*. Professor Noel Baker, M.P., a delegate to last year's assembly of the League of Nations, has stated that the League is aware that "the smuggling and distribution is carried on by a great international gang who have a stupendous capital behind them," while the exposures of the Naarden factory in the Netherlands last year and the more recent revelation of enormous exports of dangerous drugs from Switzerland to Egypt bear witness to the fact that smuggling of narcotics is no less prevalent in the West than it is in the East.

STANDARDIZATION OF CINCHONA FEBRIFUGE.

THE provision of an efficient cinchona preparation at the lowest possible price is of great importance for antimalarial work amongst the natives of tropical countries. Most white populations can afford quinine salts, but their cost is prohibitive to the vast poverty-stricken populations in the tropics, who are the chief sufferers from this disease. Some of the difficulties associated with the production of cinchona febrifuge are indicated in a short article recently published by Mr. D. Hooper.[1] The Indian Government, which has produced this febrifuge for fifty years, though always regarding it as a by-product in the manufacture of quinine, originally planted *Cinchona succirubra*, which produces "red bark." This tree is easily grown and produces a heavy yield of bark, but the bark contains relatively little quinine and a large quantity of amorphous alkaloids. It is therefore suitable for the production of febrifuge, but is much inferior to other species for the production of quinine. The Dutch Government in Java adopted the policy of producing the largest possible amount of quinine, and ignored the other alkaloids. In pursuance of this policy it developed varieties of *C. ledgeriana* and its hybrids which, though not such sturdy growers as *C. succirubra*, produced barks containing a high percentage of quinine. The Indian Government followed the example of the Dutch, but continued to produce a cinchona febrifuge. The new febrifuge, however, being made from a different raw material, differs from the original in composition. Febrifuge

[1] On the Standardization of Cinchona Febrifuge. By David Hooper. *Quarterly Journal of Pharmacy and Pharmacology*, ii, 185, 1929.

made from the red bark contained the alkaloids in the following proportion: cinchonidine 40, cinchonine 30, quinine 20, and amorphous alkaloids 10. Recent samples of febrifuge, however, contain larger proportions of amorphous alkaloids and considerable quantities of quinidine. The composition of the samples suggests that they have been made from the residual liquors of Ledger bark from which the quinine has been extracted. As far as is known the various alkaloids of cinchona have an approximately equal antimalarial action, and hence one form of febrifuge may be as good as another. If, however, cinchona febrifuge is to be recognized as an official medicine it must conform to some definite standard, for otherwise it is impossible to guard against wholesale adulteration. For the adoption of such a standard the present time, while the *British Pharmacopoeia* is undergoing revision, is particularly favourable, but as a first step it is important to estimate the relative efficacy of the individual cinchona alkaloids and of various mixtures of these alkaloids. Much valuable work has been done on this subject, but the problem is of such great economic importance that carefully planned investigations on a large scale should be carried out. With this pharmacological problem settled, it should then be possible for the Government plantations to decide on a policy which would produce adequate quantities of an efficient febrifuge at the lowest cost, and for the Government to arrange measures to popularize the use of such a product, and, if necessary, to subsidize its sale. It is evident that the problem is highly complex, but any reduction in the cost of efficient antimalarial remedies would confer a great benefit on the populations, not only of India, but of many tropical colonies.

OESOPHAGEAL OBSTRUCTION IN CHILDREN.

So much attention has been directed in recent years to the condition of "achalasia" of the lower end of the oesophagus that organic obstructions at other levels have perhaps been neglected. In the current number of the *Archives of Disease in Childhood*[1] Dr. Wilfrid Sheldon and Dr. Alan Ogilvie make a valuable contribution to the literature on this subject in their description of the clinical course of twelve cases of obstruction of the oesophagus, with pathological reports on four out of five fatal cases. The condition of complete atresia of the oesophagus met with during the first few days of life has been excluded, as has also the acquired type of stenosis following upon the ingestion of caustics. Of the twelve cases discussed, [illegible] showed evidence of obstruction at the level of the [illegible]nth thoracic vertebra, and the remaining two at the level of the diaphragm. The first group contained eight boys and two girls, and in all cases symptoms arose during the first year of life. Vomiting was the most prominent symptom, and dated from birth in seven out of the ten cases. This vomiting was generally effortless, and occurred during or directly after a meal; it was also subject to periodic bouts of exacerbation, and produced stunting of growth and constipation. X-ray examination in all these cases showed that the obstruction was well above the dome of the diaphragm, and seemed to lie about half-way between the bifurcation of the trachea and the cardia. From a general consideration of this situation of the obstruction and of certain pathological data, it is deduced that the most likely explanation of the obstruction is a congenital narrowing of the oesophagus, with possibly some secondary spasmodic element. The condition is probably cured by gradual growth of the parts, a process which is paralleled by the recovery from congenital laryngeal stridor. It is emphasized that in this state of affairs attempts at dilatation will only do harm, and the passage of bougies may actually convert a simple narrowing into a fibrous stricture. The correct line of treatment seems to be the institution of a fluid diet to carry the child on until the growth of the parts renders a solid diet possible. The second group of cases comprised two fatal instances of obstruction at the level of the diaphragm. In these vomiting had also occurred from birth, and varied in its severity from time to time. At both necropsies narrowing of the oesophagus was found, and in one of the cases where bougies had been used in an attempt to dilate the stricture fibrosis was also present in the wall of the oesophagus. After describing these twelve cases, and emphasizing the practical point that in making an *x*-ray examination a solid rather than an opaque meal should be employed, the authors discuss briefly the subject of cardiospasm or achalasia in childhood. They summarize the literature, and point out that some of the cases described in their paper had been originally regarded as examples of cardiospasm. Their verdict is that there is no conclusive evidence that achalasia of the cardia occurs in infancy, although it does rarely appear in later years of childhood. It is important that the distinction made in this paper should be clearly understood, for, as the authors rightly emphasize, the application of the bougie treatment, suitable for cases of achalasia, may do much harm if the condition is congenital narrowing of the oesophagus.

THE PROGENY OF SHERLOCK HOLMES.

THE birth rate is falling, and we are said to be within measurable distance of a stationary population; not so, however, among the spiritual offspring of Sherlock Holmes, whose fertility, judging from this season's publishers' announcements, far from abating, seems to be on an ever-steeper upward grade. Some allowance must be made, indeed, for the control exercised upon the detective population by a public growing in fastidiousness as it increases in sophistication. So exacting are the demands this public makes on its detectives that soon all but the most skilled among them may be forced into retirement or, at best, to move into another world, the world of sensational fiction, where he-men are he-men, and an unerring aim is of greater survival value than "the little grey cells." Even to-day there are signs that from the apparently undifferentiated mass of police novels there are emerging two quite separate evolutionary streams, the one tending towards a literature of growing intellectual complexity, the other towards a more lively literature of swiftly moving incident. Both of these classes are likely to appeal to a large public, for each fulfils certain clearly defined psychological needs, different indeed in their origins and manifestations and in their relative intensity among different individuals, but alike in seeking gratification in ways that are simple and socially permissible. Stated broadly, these needs are for intellectual certainty and for excitement and danger, and in so far as, speaking generally, those persons who feel the one need are little troubled by the other, the tendency in detective literature will be to produce fewer and fewer hybrids, but gradually to breed two distinct homozygotic strains, the one carrying the quality of logical analysis, the other of romance and adventure. To the former will turn persons given to philosophic speculation: indeed, so extensive already is the literature of almost pure detection that even now the intelligentsia forms a large part of the detective-story reading public. Bewildered by the mysteries of the universe, which have a way of becoming more complex with every fresh discovery of science; finding in even the simplest problem elements to baffle the mind; knowing so much and understanding so little; forced by their own philosophic conceptions to doubt even the evidence of their own senses—men and women of this class seek relief in a kind of problem for which they

know beforehand that a satisfactory solution will be forthcoming. The intellectual reader of detective tales does not ask for romance and adventure; he finds more than enough romance in a single atom; his adventure is of the spirit. He asks simply for nuts to crack, the harder the better, and he imposes upon the author but one restriction: that he shall be impartial between detective and reader, and give no help to the former that he denies to the latter. The story of pure analysis is valuable in affording brief respite from the philosophic perplexities which otherwise distract the mind and torture the spirit. The doctor, it may be supposed, belongs to the class of intelligentsia, but in the detective story he finds the added attraction that many of its problems are medico-legal in essence. Dr. Watson never mastered the methods of his great colleague, but to-day Dr. Thorndyke tackles and solves some of the most ingeniously conceived problems to be found in the whole range of detective fiction. Readers of the pure "thriller," unlike those of the detective story, ask for no problems to solve; they ask simply for some way of escape from the deadly security imposed on them by a well-ordered society. Their need is for a succession of hairbreadth escapes, and in the stories they favour, the element of detection, if present at all, is fortuitous and unimportant. Deep in their hearts is a thwarted desire for adventure, which, failing fulfilment in reality, demands fulfilment in fantasy. It may well be that in the capacity of the ordinary man and woman for fantasy, for identifying themselves with the characters of romance, is to be found one of the forces that make for social stability.

PREPARATION OF SCIENTIFIC PAPERS

For those who have something to say on a scientific topic, and wish to put it in good form, there is nowadays no lack of guidance. Sir Clifford Allbutt's admirable book on the composition of scientific papers[1] should be read and re-read. Though mainly concerned with words and phrases, the purpose of this little medical classic is "literary only so far as to insist on the qualities of precision, clearness, and definition." The would-be medical author's education is incomplete until he has digested Allbutt's *Notes*. Much good advice, technical and general, will be found also in a book by Dr. G. H. Simmons and Dr. Maurice Fishbein,[2] which presents the fruit of long experience in the editing of medical periodicals. There is also Mrs. M. H. Mellish-Wilson's small manual on the preparation of medical papers,[3] and Sir Humphry Rolleston's pamphlet on the writing of theses for medical degrees.[4] All these first-aid primers are, we believe, still in print, and if they were better known we should have less cause to regret the "curious disregard of the literary amenities displayed by a large number of members of the medical profession who send communications for publication." Another pamphlet, covering part of the same ground, was drawn up some years ago by the Medical Research Council with the object of persuading authors to keep the cost of publication of reports down to the lowest figure. A revised edition of these practical notes on the preparation of scientific reports has now appeared[5]; it is not being placed on sale, but a wide distribution has been made by the Council among research workers in the medical field. The advice given is based on experience gained in the production of more than 130 numbers of the Special Report Series. Before proceeding to small points of detail, the Council in this new edition urges that no effort should be spared in reducing the length of scientific papers and reports to the smallest compass consistent with clarity and effectiveness. Medical editors generally will agree with the Council that in the revision of manuscripts submitted to them a 10 to 20 per cent. reduction in length can very often be effected "by attention to arrangement of matter and by avoiding redundant or reduplicated sentences. Brevity can also be gained by using short English words in the place of longer words, often of Latin origin, or of groups of words." A string of examples to illustrate this point is given in an appendix. We are aware that clarity and brevity are not necessarily the same thing, but the scientific effect and literary form of a paper can always be improved by clearing away "the litter of idle words." Why write "a considerable amount of" when "much" is meant? Every medical author should learn to use the pruning knife. "A 10 per cent. reduction in the size of every paper would mean an equivalent gain in space for every library in the world, as well as in the time of all the readers concerned."

MECHANICAL PROBLEMS OF RADIUM THERAPY.

THE comments of the coroner on a recent case, where a platinum filter (screen) containing 50 mg. of radium in a needle, which had been placed in a new growth of the nose, found its way into the lung, have attracted widespread attention to a risk which those accustomed to the handling of radium in this form have long appreciated. In the case reported the radium made its way well into the periphery of the lung so that extraction through the bronchoscope, though attempted, was found impossible. Removal through the chest wall after radiographic localization was comparatively easy, but associated with grave risks of pleural infection, from which eventually the patient died. As is customary, the head of the filter—to the eyelet of which the retaining wire was attached—was screwed into the main body containing the radium needle, the screw thread being fine and having about three turns, and it is evident that during insertion and the subsequent movements of the part, sufficient rotatory twist happened to undo the screw completely, thus detaching the body of the filter from the head and leaving it free. Accidents of a similar kind, if with less serious results, have been known to occur in other cases; and it is very necessary, therefore, to reconsider the whole technique of the use of radium needles and tubes. The methods commonly employed in treatment by radium are: (*a*) superficial application by special plaques, a method confined almost entirely to dermatologists, since the rays are unfiltered; (*b*) superficial application by needles distributed in some filtering or dispersing material; (*c*) insertion into the tissues of radium needles (partially or completely filtered) and of "radon seeds"; (*d*) insertion into the lumen of viscera of radium tubes and filtered needles; (*e*) massive irradiation by "bombs." It will be seen that the present question only concerns those methods in which needles and tubes are inserted, and it will probably be argued by many that such methods can be easily supplanted by the use of bombs and radon seeds. There are many reasons, however, technical and economic, why needles will continue to be used extensively for some time to come, despite the difficulties which may arise through the fact that they must be retrieved. The ordinary radium needle is constructed of platinum (Monel metal is sometimes used in America), alloyed with iridium—10 per cent. for the body and 25 per cent. for the trocar point—to give the requisite degree of hardness; the point is screwed into the body, after the insertion of the radium, and then hard soldered in position; there is therefore no possibility

of the point being detached in use. Platinum is adopted for three chief reasons: (1) its high atomic weight renders it possible to obtain efficient screening in a needle of small bulk; (2) it is durable and resistant to corrosive action; (3) it is indestructible at temperatures likely to be reached in an ordinary furnace. For the production of screw threads which will retain their efficiency for long periods of wear it is not, however, as suitable as some other metals, and for this reason, among others, the iridium is introduced. The screens or filters are made of any metal—gold, silver, etc.—of the requisite thickness, but here again, for the reasons given above, platinum is most commonly used. The heads of these filters could, of course, be hard soldered on to the bodies as in the case of the needles, but their general utility would then be enormously reduced, since it would be impossible to apply the same radium without the screen, or in any other dosage. The problems therefore confronting the designer and user of radium needles are two—to render the removal of the needle easy, certain, and fool-proof, and to guarantee that the apparatus cannot come apart while in the tissues. For the removal of needles, wires and threads are used, but neither can be considered fool-proof, quite apart from the risks incurred by sisters and nurses in the tedious and oft-times prolonged process of threading them into the small eyelets. Wires sometimes snap and are apt to be very irritating and uncomfortable to the patient; indeed, in some situations they cannot be used at all; threads chafe and break under the strain of extraction, which is very often considerable owing to the growth of tissue round them during the interval between insertion and extraction. Really thick thread would obviate this difficulty if it were possible to thread it through an enlarged eyelet, which could probably be designed without in any way weakening the head of the needle or diminishing its radiating power. A compound thread containing fine flexible strands of wire interwoven with the thread, after the manner of flex, might be within the possibilities of the manufacturer. The difficulty with the screens also should not be hard to overcome. The principle of the lock-nut could be applied; and the head, once screwed up, could be prevented from rotation by a small spring clip or a traversing pin. It would be simple to have an eyelet at each end of the capsule, the eyes being connected by a shallow groove on each side, so that the thread could be passed through both ends, while causing no obstruction to insertion and interfering but slightly with the radiating power. There is indeed no need for the capsule to be made in two parts, since the needle, itself threaded, could be inserted from the near end and held in position by a spring collar. Finally, the adoption of double threading (perhaps in distinctive colours) is always to be advocated and in many institutions is a routine procedure. If it is an easy matter to prevent nuts from loosening when subjected to the vibration and strains of a motor engine, it should be well within the capabilities of the radium tube designer to make a really fool-proof needle and capsule, and after the publicity given to the present case there is not likely to be much delay in its production.

REGIUS CHAIR OF MEDICINE AT ABERDEEN.

THE Regius Professorship of Medicine in the University of Aberdeen is the oldest foundation for the teaching of medicine in Great Britain. Up to now it has been a part-time chair at £850 a year. Henceforth it is to have a salary of £1,200 attached to it, in view of the professor being expected to devote more of his time than hitherto to teaching and research, while additional assistance and facilities for research are to be provided. The holder of the chair is an honorary physician to the Royal Infirmary of Aberdeen, with charge of beds. The appointment to the chair is made by the Crown on the recommendation of His Majesty's Secretary of State for Scotland.

MEMBERS of the British Medical Association will be glad to know that Sir Ewen Maclean, immediate Past-President, has returned safely from his successful visit to New Zealand and Australia (when he attended the Australasian Medical Congress at Sydney as official representative of the Association at home), and also to the Ceylon, Bombay, and Egyptian Branches on his way home.

NEW YEAR HONOURS.

THE list of New Year Honours which was issued as a special supplement to the *London Gazette* of December 31st, 1929, includes the names of the following members of the medical profession, to all of whom, and in particular to Dr. Andrew Balfour, we offer congratulations.

K.C.M.G.

Lieut.-Colonel ANDREW BALFOUR, C.B., C.M.G., LL.D., M.D., F.R.C.P., Director of the London School of Hygiene and Tropical Medicine and member of the Colonial Advisory Medical and Sanitary Committee.

Sir JAMES CRAWFORD MAXWELL, K.B.E., C.M.G., M.D., Governor and Commander-in-Chief of Northern Rhodesia.

K.B.E. (Civil).

The Honourable STANLEY SEYMOUR ARGYLE, M.B., lately Chief Secretary and Minister of Public Health for the State of Victoria.

Knight Bachelor.

Professor TEMISTOCLE ZAMMIT, C.M.G., M.D., D.Litt., Curator of the Museum, Malta. For scientific services.

C.B. (Military).

Surgeon Rear-Admiral ROBERT WILLIAM BASIL HALL, O.B.E., R.N.

Major-General DAVID HARVEY, C.M.G., C.B.E., M.D., K.H.S. (late R.A.M.C.), Director of Pathology, War Office.

Colonel ARTHUR BROWNFIELD FRY, C.I.E., D.S.O., M.D., I.M.S., Assistant Director of Medical Services, Presidency and Assam District, India.

C.I.E.

Lieut.-Colonel WALTER VALENTINE COPPINGER, D.S.O., M.D., F.R.C.S.I., I.M.S., Inspector-General of Civil Hospitals, Central Provinces.

Lieut.-Colonel ARTHUR FRANCIS HAMILTON, M.B., F.R.C.S., I.M.S., Professor of Midwifery, Grant Medical College, Bombay.

C.V.O.

Sir GEORGE WASHINGTON BADGEROW, C.M.G., M.D., F.R.C.S.

HERBERT STANLEY FRENCH, C.B.E., M.D., F.R.C.P.

O.B.E. (Military).

Surgeon Commander WILLIAM INNES GERRARD, M.B., D.P.H., M.R.C.P., R.N. (ret.).

O.B.E. (Civil).

HAROLD ARMSTRONG CROUCH, M.C., M.R.C.S., L.R.C.P., Medical Inspector, Upper Nile Province, Sudan.

WILLIAM ALFRED STEDWELL LAMBORN, M.R.C.S., L.R.C.P., Medical Entomologist, Nyasaland Protectorate.

CHARLES JOHNSTON SMITH, M.B., Senior Surgeon, Singapore.

M.B.E. (Civil).

Mrs. EVA COTCHING, M.B. For infant welfare work at Haifa, Palestine.

Major ALFRED BALDWIN DESOUZA, Indian Medical Department, Resident Medical Officer, Gokuldas Tejpal Hospital, Bombay.

JOHN YOUNG MCFADYEN, M.D., Magistrate and Medical Officer, Anguilla Island, Presidency of St. Christopher and Nevis.

Kaisar-i-Hind Medal (First Class).

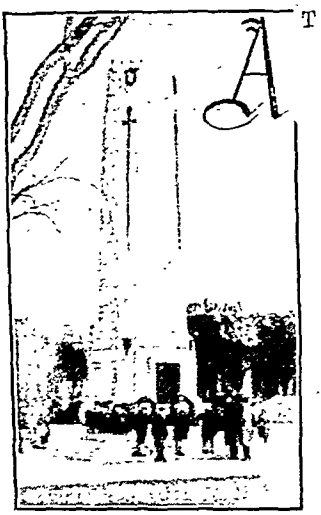
Miss MARY LONGMIRE, M.B., Ch.B., Lady Doctor in charge of the Church of England Zenana Missionary Society Hospital, Khammamett, Hyderabad, Deccan.

Service Promotions.

Royal Navy: Surgeon Commanders to be Surgeon Captains: FRANCIS J. GOWANS, M.B., B.S.; LEONARD WARREN, O.B.E., M.B., B.S.; SHELDON F. DUDLEY, O.B.E., M.D., B.S., M.R.C.P., D.P.H.

Royal Air Force: Squadron Leader THOMAS JAMES KELLY, M.C., M.D., to be Wing Commander.

A baronetcy has been conferred upon Sir T. GREGORY FOSTER, Provost of University College, London, and recently Vice-Chancellor of the University of London.



The recipients of the M.B.E. (Civil) include also Mr. D. H. J. NICHOLAS, Indian Medical Department, in charge of Government House Dispensary, Madras; and Miss ELSIE HUGHES, Secretary to Lord Dawson, for services during His Majesty's recent illness.

NINETY-EIGHTH ANNUAL MEETING

of the

British Medical Association.

WINNIPEG, 1930.

THE CENOTAPH, WINNIPEG.

AT the invitation of the Canadian Medical Association, the ninety-eighth Annual Meeting of the British Medical Association will be held in Winnipeg next summer, under the presidency of Dr. W. Harvey Smith, Professor of Ophthalmology in the Manitoba Medical College, who will deliver his address to the Association on the evening of Tuesday, August 26th. The scientific and clinical business of the meeting is being organized in fourteen Sections, which will hold their sessions on Wednesday, Thursday, and Friday, August 27th, 28th, and 29th, the mornings being given up to discussions and the reading of papers, and the afternoons to demonstrations and special addresses. The names of the Officers of Sections are given in this week's *Supplement*, together with other preliminary information, and further details of the arrangements will appear from time to time in later issues. Members who propose to take part in the Winnipeg Meeting should write for particulars about the journey by sea and land to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, London, W.C.1. The British Medical Association has twice before met outside the British Isles, and on each occasion in a Canadian city; the Annual Meeting of 1897 was held in Montreal, and that of 1906 in Toronto. We publish below the first of a series of historical and descriptive articles on Winnipeg and its medical institutions, contributed by Dr. Ross Mitchell.

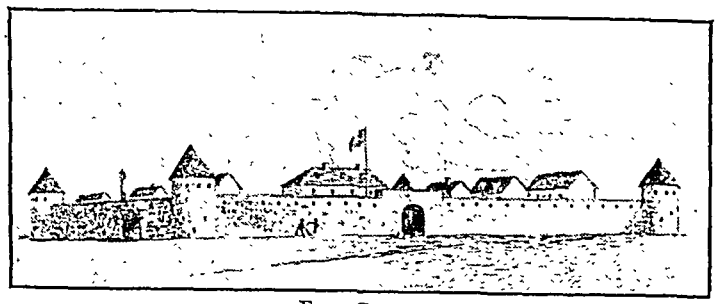
WINNIPEG: ITS EARLY HISTORY AND INDUSTRIAL DEVELOPMENT.

WINNIPEG owes its situation to the junction of two rivers. In the post-glacial period Lake Agassiz covered what is now Manitoba as well as parts of Saskatchewan, Western Ontario, North Dakota, and Minnesota. Since the ice-belt at the north of the lake prevented the passage of the waters into Hudson Bay, the great basin spilled southward by the Red River Valley, and reached the Mississippi. The old beaches of Lake Agassiz are still plainly to be seen, and the finer deposits offshore make some of the flattest and most fertile prairies. The final separation of the ice sheets permitted the waters to flow north-east, but remnants of Lake Agassiz still remain to form Lake Winnipeg and other Manitoba lakes. The Red River, which in former days flowed southward, now flows northward into Lake Winnipeg, which in turn drains by the Nelson River into Hudson Bay. The Assiniboine River, rising in Saskatchewan, flows eastward and joins the Red River forty miles above Lake Winnipeg. With these points in mind the reader will appreciate the topography of the country about Winnipeg, and the meanderings of the two rivers.

HISTORICAL.

So far as is known, the first white man to reach the spot where Winnipeg now stands was La Vérendrye, a native of Three Rivers, Quebec, who saw service in America and Newfoundland, and fought at the battle of Malplaquet, where, with nine wounds, he was left for dead on the field. Still seeking adventure in the peace that followed, he returned to Canada, and in 1738 voyaged by water from Montreal to discover a route to the Western Seas and to open up, for France, trade with the Indians of the plains. Travelling up the Red River from Lake Winnipeg, he reached the Assiniboine and passed up the latter to establish Fort La Reine near the present town of Portage la Prairie. He was shortly joined there by De Lamarque, one of the party, who had meanwhile built at the confluence of the rivers a small post called Fort Rouge. A suburb of Winnipeg still bears this name.

Some years after the British conquered Canada the North-West Company of Montreal pushed forward from their post at Fort William on Lake Superior, and, passing over La Vérendrye's route, established several trading posts from about 1780 onwards. In 1807 one of these, called Fort Gibraltar, was erected at the junction of the Red and the Assiniboine rivers.



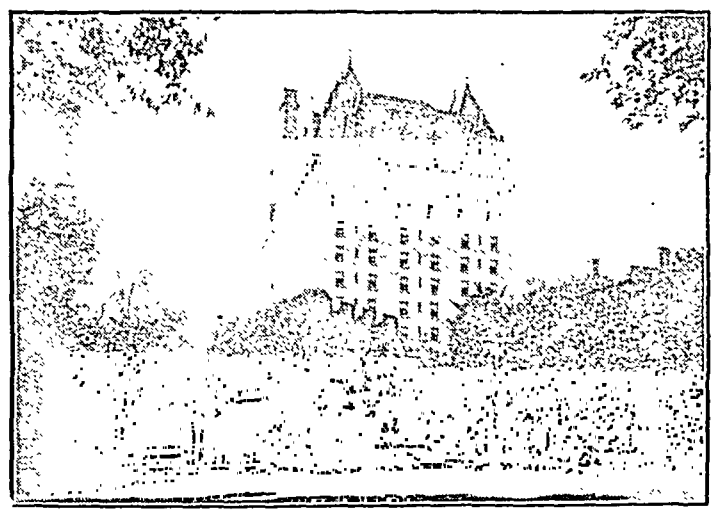
Following the year 1800, "the Governor and Company of Adventurers of England trading into Hudson's Bay," who had for over a century been extending their huge dominion from the Bay, established posts on the Red and Assiniboine Rivers. In 1811 this company conceded to the Earl of Selkirk the privilege of placing a colony on the Red River, granting him for this purpose some 116,000 square miles of the surrounding country. The first of these settlers sailed from Stornoway, Scotland, in 1811, and wintered at York Factory on Hudson Bay, continuing a journey of much suffering and hardship to reach their destination in 1812.

For years there had been bitter trade opposition and personal animus between the men of the North-West Company and those of the Hudson Bay Company. The advent of the Selkirk settlers intensified this feeling, and the North-West Company made it known that they intended driving the settlers out, since land settlement was detrimental to fur trading. The culmination of the feud was the tragedy of Seven Oaks, when Governor Semple of the Hudson Bay Company and a score of Selkirk settlers were killed. A monument marks this spot.

In 1821 the two great companies amalgamated under the title of the Hudson Bay Company. The next year Fort Gibraltar, which had been destroyed, was rebuilt and christened Fort Garry. It stood until 1882, when it was pulled down, with the exception of the north gateway,

which has been preserved in a small park. In 1831 the company commenced building Lower Fort Garry, twenty miles further down the Red River. This stone fort, with its buildings, wall, bastions, and many interesting relics, happily has been preserved, and forms a link with the past.

In 1869–70 occurred the first Riel rebellion. The French half-breeds, protesting against the surrender of the rights of the Hudson Bay Company involved in Canadian confederation, formed a provisional government. Riel seized Upper Fort Garry and terrorized the people of the district until forced to fly to the United States by the arrival of the Wolseley expedition. This force consisted of the 60th Rifles and other English Regulars, together with Canadian Militia from Eastern Canada. The troops were quartered for some time in the Lower Fort.



FORT GARRY.
(From a drawing made June 12th, 1845, by Alexander H. Murray.)

Nor was this the first time that English troops had been in the Fort Garry settlement, for in 1846 Colonel Crofton, with some 400 men, including a wing of the 6th Foot and detachments of artillery and Royal Engineers, had been dispatched at the request of the Hudson Bay Company, owing to the threat of war between Great Britain and the United States over the Oregon boundary question. The force remained for a year, and following this some British pensioners were sent out, many of whom remained in the country.

The village of Fort Garry was incorporated as the City of Winnipeg in 1873, and since then its growth has been steady, accelerated in 1883 by the arrival of the main line of the Canadian Pacific Railway, gradually followed by other lines, including the Canadian National Transcontinental. The earlier settlers came from Ontario, while later settlers came from the British Isles, the United States, and European countries.

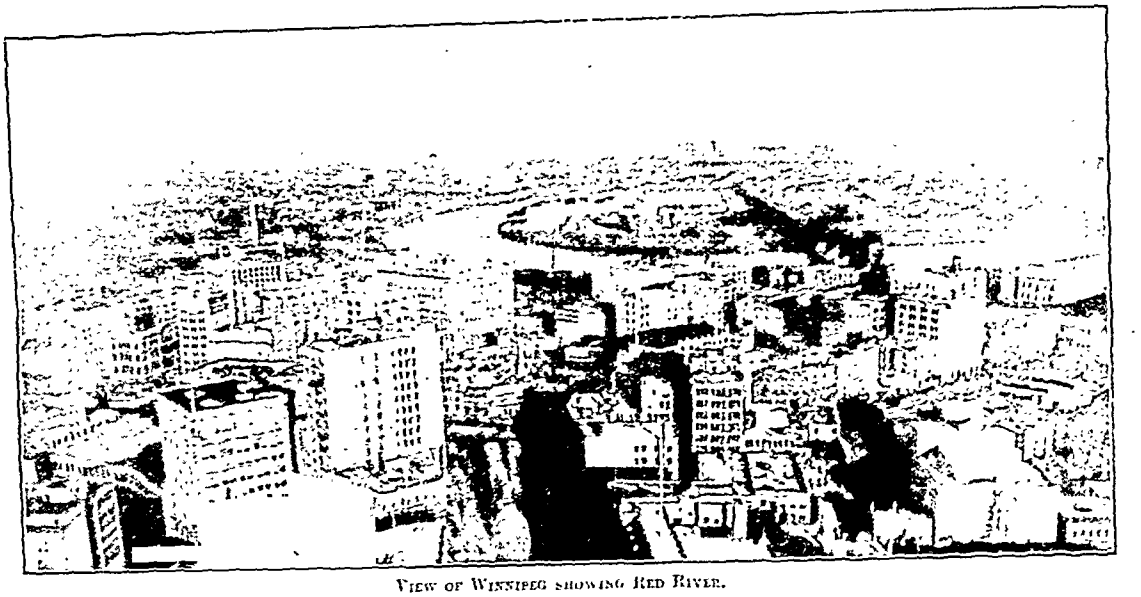
INDUSTRIAL ACTIVITIES.

For a quarter of a century Winnipeg metaphorically carried its eggs in one basket. The basic industry of the Canadian West was agriculture, and with the success or failure of the crops the city's prosperity rose and fell. In recent years, however, the yield of the soil has ceased to be all-important. The development of hydro-electric power, the discovery of minerals in the northern part of Manitoba, and the completion of the long-discussed railway line to Hudson Bay have directed activities into new channels.

FORT GARRY HOTEL, WINNIPEG, SHOWING ORIGINAL FORT GARRY.
(Photo by courtesy of the Canadian National Railways.)

Winnipeg is naturally the hub of all industrial activity for the province, and by the way it has gone ahead in the last five years it reflects the general progress made by Manitoba as a whole. Material contributory factors have been the great development of hydro-electric power: mining activity, which includes investment of tens of millions of dollars, particularly in the north country; railway expansion, giving access to new territory and fresh resources; increase in industrial development with mounting pay rolls; and greater returns from agriculture through diversification in farming.

Winnipeg is also the centre of the grain trade of the whole country, as well as of many of the allied industries which have developed. Here are located the great selling agencies of the West's grain crop, the Wheat Pool and the Winnipeg Grain Exchange, which divide the handling about equally between them. It is the seat of the Canada Grain Commission, which is responsible to the Dominion Government for the administration and interpretation of the Canada Grain Act. The bulk of the grain is inspected at this point for grade standards in the largest and most important plant of the kind in the world. And from this centre the transportation departments of the two great railway systems direct the gigantic task of moving the crop each year.



Wheat Production and Export.

Brief comment on the leading activities of Manitoba and its capital city may not be without interest. The only commodity it paid the earliest settlers to "pack out" was fur, and it was not until after 1870 that wheat began to be thought of as an export. Indeed, the very fertility of the soil was seriously questioned up to that time except along the silt-enriched banks of rivers. Neither was the fluidity of grain recognized, and men transported the early crops in jute bags. Other methods of handling were equally laborious.

The advent of the railroad made export both possible and profitable, and rapidly mounting growth in production was met by the gradual evolution of the most complete bulk handling system, participated in by the banks, the transportation companies (rail and navigation), the Government, and the grain trade. Proper handling has meant the provision of enormous storage capacity, with facilities for weighing, scouring, cleaning, drying, special binning, and efficient loading. It has meant the training of thousands of persons for the diverse phases of handling from the time the grain leaves the farmer's wagon-box until it passes out of the country. The heart of all this activity is Winnipeg.

Wheat production in 1928 reached the high mark of considerably more than half a billion bushels, and elevator storage capacity stood at nearly half that figure, including harbour front terminals as well as the interior elevators into which the farmer weighs. The Wheat Pool last year erected a handsome new headquarters for its central selling agency at Winnipeg. In 1928 the Winnipeg Grain Exchange thrust out a new half-million-dollar wing, and is again cramped for trading space. It is the largest cash grain market in the world where the greater part of the trading is backed up by the actual grain. The bulk of the 1928 export of grain—almost half of what the whole world consumed—was handled through Winnipeg.

The story of persistent research and experimentation in connexion with the evolving of an all-round suitable kind of grain is a romance in itself, which can barely be touched upon. Some years ago three heads of wheat were saved by an Ontario farmer, out of a sample of seed grain sent him from Scotland, and since traced to the Ukraine. These three heads became the ancestors of "Red Fife," which in turn, bred and crossed with Russian and other hardy northern varieties, brought forth "Marquis" wheat, the present standard. "Marquis," whilst of excellent milling

VIEW OF WINNIPEG SHOWING RED RIVER.

quality, early maturing, and frost-resistant, is not "rust" proof, and so a fresh intensive research is going on at the present time in the Government Rust Research Bureau, located at Manitoba Agricultural College, for a variety which shall retain all the good qualities of "Marquis" and be rust-resistant as well. Success in this instance will mean a saving of untold millions to the country.

Development of Hydro-electric Power.

The rapid increase in industrial production in Manitoba, which last year surpassed agricultural production by 10,000,000 dollars, is due in the main to one great economic factor—the development of plentiful and cheap hydro-electric power. Besides the benefits accruing to the city from the added pay rolls, it has become the first electrical city of the world, with an average of 3,384 kilowatt hours' annual consumption per residence. The cost is the lowest on record—a shade above three-quarters of a cent per kilowatt hour, as against an average cost of 7.16 cents in 172 representative American cities. Towns and villages throughout the province are rapidly being supplied with power, and the erection of transmission lines is keeping pace with the harnessing of waterfalls. Pulp and paper mills are included among the industrial enterprises which have followed in the wake of power production.

The total resources of the province in hydro-electric power are placed at 5,000,000 horse power, of which 3,000,000 are on the Nelson River, convenient to the mining belt of the north, and 800,000 on the Winnipeg River, within easy transmission of Winnipeg. The total development, so far, consists of three sites on the Winnipeg River, producing 308,000 horse power. Two other sites on the same river—Slave Falls with 90,000 horse power and Seven Sisters Falls with 225,000 horse power—are being developed, as well as one 50,000 horse-power hydro-electric plant in the northern mining area.

The full story of how the first of the equipment and machinery for the development of hydro-electric power was "packed" into the wilderness on the backs of men, of the overcoming of swamps and morasses, of mosquito-infested trails, of the excavating of thousands of tons of rock, and of the damming of lakes and rivers, may never be told as it deserves. But one thing is certain, and that is that the great waterfalls, beside which the toilers of an earlier era sometimes dropped dead under their 200-pound load per man during the portages, from now on will not be called "majestic and frightful," as Daniel Harmon said of them in his famous journal in 1800, but "majestic and useful."

Mineral Wealth.

The presence of valuable copper deposits along the Coppermine River on the Arctic border, has been known since the discoveries of Samuel Hearne in 1771-72, but they are still inaccessible. Similarly, the buffalo hunters who rode the trails on the great hunts in the fifties and sixties, knew of the lignite deposits in the Souris Valley on the south-western Manitoba border, but it was not until the railroad came that the knowledge could be put to general use. Something less than one-fifth of the surface of this province is arable, leaving an immense area in which it was possible to prospect for minerals, metallic and non-metallic, and yet it is a bare eighteen years since the beginning of Manitoba's metal-mining development, although production of non-metallics commenced earlier.

The returns from metallics have not been large so far, and will not be until the great plants, now being erected at enormous cost in the hinterlands of the province, bring the properties they are designed to serve into production. The largest of these are the Flin Flon and the Sherritt Gordon properties north of the Pas near the Saskatchewan border. The Hudson Bay railway cutting through this region is now an accomplished fact after more than forty years of "talk," and branch lines from it connect with both these properties. The Island Falls power site, ninety miles distant, now under development, will furnish the needful power.

When the Flin Flon mine is brought into production 3,000 tons of ore will be treated daily, with an approximate annual production of 30,000,000 pounds of copper and 50,000,000 pounds of zinc, as well as values in gold and silver, according to information supplied by the industrial development department of the Canadian Pacific Railway. A concentrator and smelter is now being erected to treat these ores. The Sherritt Gordon property, which is a near neighbour, will have a higher yield per ton, and contains copper-zinc ore with values in gold and silver also. A 1,500-ton concentrator is under construction on the property, while the copper concentrates will be smelted at the Flin Flon smelter. The "Mandy" is another property in the same area from which considerable high-grade ore was taken in 1917-19, with diamond drilling under way at present for the location of further ore bodies.

In the southern Manitoba mining field the Central Manitoba Mines is the only producing concern at present. A 150-ton mill has been in operation here since 1927, and gold to the value of 770,483 dollars was shipped to the mint at Ottawa last September. Hydro-electric power from Great Falls on the Winnipeg River supplies this plant. Other mines in this area, where developmental work is now

taking place, are the San Antonio and the Gem Lake. Minerals, other than those named above, which have been discovered in the province are tin, silver, arsenic, cobalt, iron, lead, nickel, molybdenite, tungsten, and beryllium.

For some time past the province has had a very real asset in the non-metallic minerals, which have been responsible for more than 75 per cent. of the mineral production to date. Of these, the group of structural and building material is the most important. First in rank is building stone (Tyndall stone), which is a limestone quarried thirty miles east of Winnipeg, and of so high a quality that it is being shipped to all parts of Canada. It is seen in Manitoba's public buildings and many of its business houses. The brick and tile industry is also important; gypsum has been produced for a number of years; and sand, suitable for glass manufacturing and moulding, is also available in large quantities.

A discovery which may be of considerable importance commercially is that of large quantities of lithium ore along the Winnipeg River, near the Ontario boundary. Considerable development of this find has already taken place, and ore has been shipped to Europe for extracting the lithium. The discovery has brought Manitoba conspicuously before other parts of the world in view of the fact that here is one of the largest sources of supply of a non-metallic mineral whose uses are rapidly increasing. Other non-metallics found in the province are limestone, granite, marble, bentonite, feldspar, garnet, salt, peat, coal, oil, and gas. There has, however, been very little production of any of the latter named.

A great deal of prospecting is now taking place, and it would not be surprising if new discoveries of first importance were made within the next few years, more especially in the non-metallic minerals in the northern part of the province.

MEDICINE AND PUBLIC HEALTH IN THE NEW PARLIAMENT.

THE Labour Government has been in office nearly six months, during which the new Parliament has been in session for twelve weeks. Both in the Ministries and in the House of Commons business has been heavy. As the Government was pledged to take urgent measures for the relief of unemployment and stimulation of work, it might have been expected that medical subjects would have been neglected. Actually they received a good share of attention, happily without becoming centres of party controversy. Almost at the beginning the new House made a united effort for medical progress when it authorized a vote of £100,000 for the purchase of radium. Mr. Greenwood, the Minister of Health, has given the Mental Treatment Bill precedence over the promised Housing and Slum Clearance Bill. This was partly because the former measure, not being opposed on party lines, could be introduced in the House of Lords, but the precedence given it indicates an interest in medical and public health subjects, which the Minister has shown in other ways. The Home Office, under Mr. Clynes, has given sympathetic attention to medical issues relating to factories and factory inspection. The appointment of Dr. Drummond Shiels as Parliamentary Under Secretary, first to the India Office and then to the Colonial Office, provides a new link between medicine and the Whitehall departments dealing with the tropics.

On both sides of the House the "back benchers" show no hostility to the medical point of view, and in many cases their questions display a desire to see the Government do more for public health. There have been practically no questions directed against vaccination and experiments on animals. At the start of the session Dr. Fremantle excited some Labour members by warning the Government that money was being eaten up by housing which would benefit national health far more if used on other services. During a recent sitting Dr. Vernon Davies corrected a lurking obsession among trade unionist members of Parliament by informing them that the medical profession had no trade union. But no antipathy has been shown by the Labour party towards the profession. That party contains leading and orthodox medical men among its members in the House of Commons. Two, Dr. Salter and Mr. Somerville Hastings, have been elected respectively chairman and honorary secretary of the Parliamentary Medical Committee, membership of which is now restricted to members of Parliament or peers with a medical qualification. These number about a score, and the profession has never been more strongly represented in Parliament.

If this Government and Parliament last their full term of four or five years—a matter on which all parliamentary observers feel doubts—medical proposals of outstanding importance will be put before both Houses. During the debate on the Widows' Orphans' and Old Age Pensions Bill Mr. Greenwood announced that a Cabinet Committee was considering the various State insurance schemes, the gaps between them, and their correlation with other forms of social service outside insurance. This last phrase hints apparently at the Poor Law and the voluntary hospitals. Mr. Greenwood spoke of coming proposals to enlarge the field of national health insurance. He said that the Government might ask the House to consider provision of medical and midwifery services in pregnancy and childbed to wives of insured men and the increase of specialist services to insured persons. Mr. Somerville Hastings has gone further in convening meetings at the House of Commons to promote the movement for a national medical service. Such a service is an objective of the Labour party, but forms no part of the Government's programme in the present Parliament. Incidentally it should be recorded that Mr. Greenwood has adopted, and is preparing to carry out, Mr. Chamberlain's plans for rearranging the hospital and institutional accommodation at the disposal of local authorities and for securing its use in co-ordination with the voluntary hospitals. A Midwifery Bill, introduced by Mr. Alpass, a Labour member, was looked upon as representing the policy of that party, but it has not met with success or with general acceptance.

The Mental Treatment Bill quickly passed through the Lords, where it was introduced on November 19th, and its prospects are good, though legalists in the House of Commons may urge the arguments put unsuccessfully in the House of Lords by Lord Brentford for retaining the certifying magistrate instead of relying on medical opinion. The bill was ably handled in the Lords by Earl Russell, and strongly supported by Lord Dawson. Together they convinced the House of the need for facilitating early treatment without certification. Earl Russell, in his speech, recognized the importance of offering greater protection to medical men who give certificates, though the provision of the bill on this point is neither clear nor universal in its application. One amendment has been made to ensure that "voluntary" application for early treatment on behalf of an adolescent shall be supported by a medical opinion. Mr. Greenwood has spoken in the House of Commons with dissatisfaction about the present provision for mental defectives. In England and Wales 28 local authorities have now provided residential institutions for these persons, but 78 had not, and others are only beginning to take action. Mr. Greenwood hopes to stimulate the backward authorities. Recognizing that cost is the chief cause of delay, he has instituted an inquiry into the possibility of reducing the expense of providing mental institutions.

Vaccination has not been much before the House of Commons, though Mr. Greenwood has announced that he is considering the whole question, including a proposal to make vaccination voluntary. He gives the proportion of parents claiming exemption for their children at 40 per cent. The Parliamentary Medical Committee has heard Sir George Newman and Dr. Hutchinson (from the Ministry of Health) on administrative aspects of the subject, and has also visited the Government lymph station at Mill Hill. The Home Secretary has answered questions from lay members concerning industrial diseases, such as conjunctivitis in silk works, aniline dye cancer, and silicosis. Amendments of the silicosis regulations are understood to be in preparation, but the Government's advisers have not accepted the assertion made by some miner members of Parliament that a detrimental "anthracosis" is caused

by coal dust. During the debate on a Children and Young Persons Employment Bill, Dr. Vernon Davies, as a former certifying factory surgeon, interested the House by contending that work in a mill during pregnancy may benefit some women. Dr. Davies has also spoken on the accommodation for seamen on British ships.

Mr. Adamson, the Secretary for Scotland, has carried through Parliament an Act authorizing increased grants for medical and nursing services in the Highlands and Islands. This measure was strongly supported by Dr. Elliot, who himself introduced a bill to permit the supply of milk to school children in Scotland to promote their health. Mr. Somerville Hastings has put a succession of questions regarding tuberculous milk, and has been informed that the proportion of cows tested in England and Wales with tuberculin is still too low to permit of general inferences. Dr. Fremantle, who is now deputy chairman of the Parliamentary Medical Committee, has concerned himself with the dangers from the dumping of London garbage on the Essex marshes and at other places in the Home Counties, and has formed a committee of members of Parliament to watch this subject.

On one other urgent issue of medical interest—the cost of treating in hospitals persons injured in motor accidents—Ministers were immovable when questioned in the House of Commons. The issue was raised in the Lords by means of a proposed amendment of the Road Traffic Bill, whereupon a promise was given that the Government would try to devise means whereby this heavy and growing charge on hospitals may be defrayed.

KING EDWARD'S HOSPITAL FUND.

DISTRIBUTION FOR 1929.

THE annual distribution meeting of King Edward's Hospital Fund for London was held on December 17th, 1929, at St. James's Palace, the PRINCE OF WALES presiding. After reading a message from the King expressing his pleasure in the fact that the Fund, for the second year in succession, was able to make an ordinary distribution of £250,000, and that the hospitals would also benefit very largely from the Thank-offering Fund, His Royal Highness said that the grand total of grants amounted to £378,734, besides the allocation of the radium purchased with Sir Otto Beit's gift of £50,000. In the first place, there was the ordinary distribution of a round quarter of a million. Last year, when this sum was reached for the first time, it was thought good policy to rest awhile, lest progress be too fast, but it was now apparent that even if the amount stayed at its present level for more than two years the Fund would not be doing its duty to the hospitals, which were continually increasing their liabilities. Grants towards the pensions scheme for nurses and hospital officers amounted this year to some £13,700. Then there was the special Thank-offering, which rendered £220,000 available for the King's Fund. Of this amount £105,000 was represented by the splendid gift of "Audax," which was to be invested, while the remaining £115,000 would be distributed in the form of grants in aid of extensions and improvements. Finally, there was the radium purchased by the King's Fund with Sir Otto Beit's gift. The 4 grams had been allocated among twenty hospitals. [It was stated in a subsequent report that 2,300 mg. had been actually delivered to fifteen hospitals, and the remaining 1,700 mg. was on its way as quickly as containers and needles could be supplied.] The Prince mentioned that that very morning a gift of £10,000 had been received from Mr. Roger C. Parr. He concluded by naming a number of persons and bodies to whom the Fund was specially indebted.

Sir COOPER PERRY, chairman of the Distribution Committee, said that 143 hospitals had made application to the Fund, two more than last year. The larger grants recommended in the ordinary distribution included the following:

Charing Cross, £4,500; City of London (Victoria Park), £3,500; East London, £3,250; Guy's, £12,000; Hospital for Sick Children, £4,150; King's College, £7,100; London, £14,150; London Temperance, £3,750; Metropolitan, £4,250; Middlesex, £2,300; Miller, £5,600; National (Queen Square), £4,275; Prince of Wales's, £5,850; Queen Mary's, £4,500; Queen's Hospital for Children, £3,600; Royal Free, £7,000; Royal National Orthopaedic, £4,500; Royal Northern, £3,800; St. Bartholomew's, £6,500; St. George's, £2,700; St. Mary's, £6,000; St. Thomas's, £10,500; University College, £8,750; West London, £5,250; Westminster, £5,100; Willesden, £3,000.

The sum available for distribution among convalescent homes not attached to any particular hospital in London had been fixed at £2,000. With regard to the special distribution of £115,000 out of the Thank-offering Fund, the committee had followed the plan of recommending large grants where circumstances demanded substantial assistance, but yet not so large as to exhaust the whole sum available, and thus unduly limit the number of hospitals participating. The names of 73 hospitals were included in this distribution; 3 received grants of £10,000 and over, 24 received grants of from £1,000 up to £10,000, and the remainder grants below £1,000. Of the purposes for which the grants were made the extension of existing hospitals was the most frequent (25); 12 were for rebuilding, reconstruction, or new and enlarged hospital buildings, 11 for additional nurses' accommodation, and 12 for enlarged out-patients' departments. The list of grants recommended from the Thank-offering Fund included:

East Ham, £2,500; General Lying-in, £2,500; Guy's (towards provision of site for out-patients' extension, and to reduce deficit on recent improvements), £3,000; King George (Ilford), £10,000; Metropolitan, £3,500; Middlesex (towards reconstruction), £14,000; Miller (to reduce deficit on extension), £12,000; Queen Charlotte's, £9,000; Royal Free, £5,500; Royal National Orthopaedic, £4,500; St. Bartholomew's (towards new operating theatres), £2,000; St. Mary's Hospital for Women and Children (Plaistow), £3,500; Woolwich War Memorial, £5,000.

Lord DONOUGHMORE, in submitting the report of the Management Committee on the Thank-offering Fund, said that the aggregate for the whole country was £629,597. The portion of this contribution which had been put to the King's Fund was, as stated, about £220,000; the contributions to the Radium Section (the object of which was to obtain the amount required for the National Radium Fund, to which the Government had promised £100,000 on a pound for pound basis) totalled £187,012; other thank-offering funds, the totals of which were included in the list, amounted to £192,478, and contributions earmarked for individual hospitals and other charities were £91,710. It was realized that the King's Fund could not put forward a claim to be regarded as the sole channel, although the hospitals of London were national institutions, but for the purpose of a thank-offering it was desirable that the public outside London should have an opportunity of selecting local charities. Therefore, provision for earmarking was made. Out of the money collected for radium, the first instalment of £100,000 had been handed over to the National Radium Trustees, to enable them to claim the Government grant, and a further £50,000 was held for their account. The balance of £37,000 would be placed at the disposal of the King's Fund for the purchase of radium to be loaned to hospitals in London. On Lord Donoughmore's motion, it was resolved that an address be presented to the King, referring to the origin, history, results, and distribution of the Thank-offering Fund, and tendering to His Majesty loyal congratulations on his recovery.

Sir EDWARD PENTON presented a report for the Voluntary Hospitals (Local Government) Committee, which is henceforth to be known as the Parliamentary Committee, and although called into being to deal with the situation created by the Local Government Act, is to remain in existence to consider any projected legislation affecting hospitals. The report described a draft scheme for a body representative of the voluntary hospitals of London to confer with the London County Council under Section 15 of the Local Government Act. The King's Fund, the teaching hospitals, and the British Hospitals Association had co-operated in the formation of a Joint Committee, a truly representative hospital body, for consultation with the council as required by the Act. The Joint Committee aimed, it was said, not merely at the fulfilment of a statutory obligation, but at providing the means for continuous consultation and co-operation between the voluntary and the county council hospitals. The scheme of representation provided that for each of the five hospital

areas in which London was to be divided there should be an area committee, composed of representatives of the voluntary hospitals, and that, for consultation with the county council, there should be a central committee for the whole county, composed partly of representatives of the area committees, and partly of representatives of special hospitals the services of which were not localized in relation to any particular area. It was also provided that the importance of teaching hospitals should be recognized by securing that each teaching hospital should be assigned to one or other of the areas, and be represented on the area committee, and that there should be a separate committee for the non-localized special hospitals. Lord MONK-BRETTON, chairman of the London County Council, voiced the cordiality with which the council would welcome such co-operation in the difficult and onerous duties before it.

Australia.

[FROM OUR CORRESPONDENT IN VICTORIA.]

Australasian Medical Congress.

THE third session of the Australasian Medical Congress (British Medical Association) was held at Sydney in the last week in September, 1929, and some account was given in the issues of the *Journal* on November 16th (p. 921) and November 23rd (p. 974). The majority of the fifteen sections met twice a day, and discussed many subjects; for the first time there was a section devoted to the study of anaesthesia. The congress was honoured by the presence of Sir Ewen Maclean, immediate Past-President of the British Medical Association, who attended as the official delegate of the Association. Sir Ewen Maclean took an active part in the discussions, and in many of his speeches showed his keen interest in the development of post-graduate work. Thanks are due to the president, Dr. C. H. Abbott, and the honorary secretaries, Drs. T. W. Lipscomb and A. A. Palmer, assisted by Dr. R. H. Todd, for the success of the congress, and for the manner in which they performed the difficult task of organizing so great a gathering.

Hospital Beds for Paying Patients.

The State Ministry has drawn up plans for the establishment of "community sections" at the public hospitals of Victoria. Mr. and Mrs. F. D. Michaelis recently asked the Premier, Sir William McPherson, to accept a gift of £5,000 to form the nucleus of a fund for the establishment of a community wing at the Alfred Hospital; the gift was accepted. It is proposed that the community wings should be conducted by a committee separate from, but appointed by, the general hospital committee, and that the financial arrangements for the community wards should be entirely distinct from those of the public wards. The community wards are to be used by private and intermediate patients, who are defined respectively as those able to pay in full or in part for their hospital accommodation and the medical and nursing fees. Questions relating to the admitting of each kind of patient will be decided by the committee controlling the community section on the recommendation of a medical practitioner. Medical fees charged to private patients will be entirely a matter of arrangement between the practitioner and the patient. The maximum amounts which may be charged to intermediate patients will be set out in a fixed table, to be drawn up by a body representative of the majority of medical practitioners in Victoria. The regulations assure to patients the right to choose their own doctor; all the reputable practitioners in a district served by a public hospital will be allowed to attend their patients in the community section.

Medical and Scientific Education in Melbourne.

The council of the University of Melbourne has appointed Dr. R. Marshall Allan, *M.C.*, to the chair of obstetrics. The new professor will devote the whole of his time to the organization of teaching and research. Under the auspices of the Melbourne Permanent Committee for Post-Graduate Work, Professor Hugh MacLean delivered, between August 12th and 23rd last, a series of lectures on gastric physiology and pathology, the diagnosis and treatment of gastric disease, some problems in carbohydrate metabolism and diabetes, vascular and renal disease, and the uses and abuses of biochemical methods in clinical medicine. The lectures were very well attended and were much appreciated. During the same fortnight a series of lectures and practical demonstrations, covering a wide range of subjects, was arranged by the post-graduate committee at the various teaching hospitals. Owing to the marked falling off of the number of students in the veterinary school, due chiefly to the poor prospect of remunerative employment after graduation, it has been decided to confine the teaching work to the first two years of the course, and to send the Victorian students to Sydney for the completion of their studies. The council of the University of Melbourne adopted the report of a committee appointed to investigate the financial position of the school; in this it was recommended that, for the present, the school should be carried on chiefly as a research institute. In recent years a good deal of research had been undertaken there, not only in connexion with the Department of Agriculture, but also with the Council of Scientific and Industrial Research, the Walter and Eliza Hall Trust, and cancer research.

Canada.

[FROM OUR CORRESPONDENT IN MONTREAL.]

Vital Statistics of Canada.

THE Dominion Bureau of Statistics has published a preliminary report on the vital statistics of Canada for the year 1928, from which the following facts are taken in respect of a population estimated as 9,645,000. The birth rate is one-tenth of 1 per cent. less than that for 1927, being 24.5 per 1,000; 3.1 per cent. of these births were illegitimate. The general mortality rate was 11.3 per 1,000, which is slightly higher than the corresponding rate in 1927, but is rather lower than that for 1926. While comparisons between the various provinces in this respect can only be legitimately made with some reservations, it is noteworthy that Quebec has the highest rate (13.8), while Saskatchewan has the lowest (7.2). There is little doubt that one disease which contributes largely to this higher mortality of Quebec is tuberculosis. This province had a record of 2,686 deaths from tuberculosis, out of a total for the Dominion of 6,481. Diseases of the heart accounted for the highest number of deaths—namely, 12,640; diseases of the arteries caused 5,644, and nephritis 5,717 deaths. Among children it is notable that there has been a considerable reduction in the mortality under the age of 5: but, even so, there is room for much more improvement, since the figures show that practically 20 per cent. of all deaths were those of infants under 1 year old, and that 25 per cent. of all deaths were those of children under 5 years of age. Maternal mortality showed no change in the rate which obtained in the previous year—namely, 5.6 per 1,000 living births. This rate was highest in Prince Edward Island and Alberta (6.1 and 6.8 respectively), and much remains to be done to bring about improvement in this respect. There are other diseases, however, which have been clearly shown to be more easily controllable, and yet they still appear statistically in unwelcome numbers; typhoid fever, for example, caused 468 deaths, and diphtheria 913.

A New Research Journal.

The ever-growing list of scientific periodicals has been recently augmented by the venture of the Research Council of Canada in issuing *The Canadian Journal of Research*, which is to be a medium for publishing the increasing number of scientific papers produced by Canadian workers. The journal was originally planned to record the work done under the auspices of the Research Council, but it is also open for suitable papers from Canadian workers not connected with it. The first two numbers contain accounts of research work on matters relating to husbandry and to biological problems, much of which has been undertaken in the Universities of Edmonton and Saskatoon.

Hospitals in Montreal.

The hospital situation in Montreal has presented itself as an acute problem for some years. There is, indeed, no exaggeration in the statement that for the last twenty years there has been no increase in hospital accommodation of any significance, and this in spite of the fact that the city has nearly doubled in population in that time: an unofficial census shows over a million inhabitants. This does not imply that the existing hospitals have not kept up with modern developments, for the leading institutions here, such as the Montreal General and Royal Victoria Hospitals, rank with the best on the continent, but they themselves have not increased in size. It has been very encouraging, therefore, to note an effort which has been recently made by the Jewish community in the city to relieve the situation. By means of an organization directed entirely by themselves, and with the aid of a grant from the Provincial Government, they have succeeded in raising more than a million dollars for the erection of a general and maternity hospital, which will contain about 150 beds, and be open to all, irrespective of race or creed. The Provincial Government has also granted 230,000 dollars towards the erection of a general hospital, to be administered under the Public Charities Act, and to be staffed by the Order of the Grey Nuns.

Scotland.

Memorial to Dr. John Thomson.

A MEMORIAL tablet to the late Dr. John Thomson, in the *Royal Hospital for Sick Children* at Edinburgh, was unveiled on December 14th, 1929, by Sir Thomas Barlow. Among those present at the ceremony were Principal Sir Thomas H. Holland, Professor G. F. Still, Dr. Robert Hutchison, Sir Robert Philip, Dr. Haig Ferguson, Professor Leonard Findlay, and Dr. Charles M'Neil, secretary of the memorial committee. Mr. J. S. Leadbetter, K.C., vice-chairman of the directors of the hospital, presided. Sir Thomas Barlow outlined the work and character of John Thomson, and said that a great reserve of quiet power, sound method, and good judgement lay behind his modest, half-deprecating demeanour. A hesitancy of speech was the outcome of a resolute determination to cultivate accuracy of statement. His work in Edinburgh had begun in 1886 as physician to the New Town Dispensary, where he soon developed a successful children's clinic, and shortly afterwards he entered on work as assistant physician to the Sick Children's Hospital. The most important item of knowledge that he had contributed to medical science was his account of pyloric stenosis in young subjects, an obscure affection of which the importance had been made clear by Thomson's exhaustive report of 100 cases under his own care. In Dr. Thomson's character there had been a genius of friendship, while jealousy and self-advertisement were unknown to him. A later phase of Dr. Thomson's career had been the earnestness with which, in the cause of mentally defective children, he set himself to engage the interest of mothers in simple methods of wakening intelligence and cultivating self-control. He would be remembered as the embodiment of wise sympathy and of a refined and delicate thoughtfulness. The memorial consists of a marble panel bearing a bronze portrait medallion of Dr. Thomson, and is placed opposite the entrance to the ward where he spent much of his life. It has been executed by Mr. C. O'D. Pilkington Jackson. It was announced that there were 117 subscribers, all medical men, from whom about £270 had been received. This provided, in addition to the memorial, a medal to be awarded by the University of Edinburgh yearly to a young graduate for original investigation bearing on the subject of children's diseases. Sir Thomas Holland, in accepting the commemorative medal on behalf of Edinburgh University, said that the work which would be done in connexion with the medal would not only be of humanitarian value but of economic importance to the community as a whole. One phase of research for which the medal would be bestowed would be related to the psychology of children, and the association of Dr. Thomson's name with this medal would be a great inspiration to students. Professor Still said that Dr. Thomson's character might be summed up in two words: "kindliness" and "sincerity." Few men had made such varied additions to the knowledge of disease in children, and Edinburgh might be proud to have reckoned among its citizens and alumni of the university such a distinguished physician, whose name would abide. Dr. Logan Turner said that Dr. Thomson's life had been one long opportunity for the consideration and elucidation of problems of disease in children, and Dr. Robert Hutchison said that Thomson's memorial was recorded in his scientific writings as well as in the lives and practice of students whom he had inspired, and who were scattered all over the globe, and, above all, in the gratitude of those to whom, as children, his whole life's work had been devoted. After the ceremony a complimentary luncheon was given in honour of Sir Thomas Barlow by the University of Edinburgh.

Gynaecological Statistics.

The governors and the medical staff of the Royal Samaritan Hospital for Women, Glasgow, formed the opinion, early in 1928, that a compilation of the statistics of patients treated in the institution might be of considerable scientific value and of general interest to gynaecologists and to other hospitals. The statistics of 2,033 patients, mainly Scottish, whose treatment was completed between April 1st and December 31st, 1928, have now been published, the diseases being scheduled under four headings —regional, general, outside the genital and urinary tracts, and conditions not classifiable under the other three headings. The material seems to have been drawn from four clinics; the number of operations performed was 1,856, with a mortality of 1.5 per cent. Etiologically the conditions from which the patients suffered are divided into: infection associated with child-bearing; infection unassociated with child-bearing; injury associated with child-bearing; new growth; errors of development; causes not belonging to any of these groups; and cases (121 in number) with no appreciable disease. Divided and subdivided in these ways, a complete list is given in Table V of the different pathological lesions encountered in the 2,033 patients. The table gives information as to the number of cases of each lesion, the condition of the patient as regards marriage and pregnancy, the number of patients operated on, the average stay in hospital, the number of cases in which one or more additional lesions were present, and the number of deaths. The next table gives the number of conditions regarded as the primary lesion in the 2,033 patients; while in following tables cases are recorded in which second or third conditions of less importance existed. A final table gives brief notes of the thirty-one fatal cases. The peculiar interest of this table is that, small though the proportion of deaths is, quite a number of the patients who died appear to have suffered from comparatively unimportant conditions. A useful reminder is given that even in plastic operations for procidentia pulmonary embolism may occur. Much of the work of preparing the schedule of diseases, and collecting, classifying, and compiling the statistics has been done by Dr. Donald McIntyre, surgeon to the hospital. He regards this record of nine months' work as an experiment, mainly for the purpose of judging if the scheme is workable. The result would seem to justify continuance of the scheme.

Increased Duties of Voluntary Hospitals.

An address was delivered recently in Glasgow by Mr. W. E. Whyte, clerk to the District Committee of the Middle Ward of Lanarkshire on the provisions of the Local Government (Scotland) Act, 1929. The lecturer spoke particularly of the great enlargement of powers committed to local authorities in connexion with hospital services. On account of the number of authorities who in the past had been empowered to make hospital provision, and the lack of co-ordination between these, there was often failure to secure an adequate hospital service. Many of the hospitals, he thought, were too small and too imperfectly equipped to be regarded as suitable, while the

accommodation for the sick poor was of a wholly unsatisfactory nature. Local authorities were now to be empowered to provide as part of their public health duties treatment for all kinds of sickness, and there would be no distinction between the ordinary sick and the sick poor. The intention was to link up local authority service with voluntary hospital service as far as this was possible, and it was not sufficiently recognized that local authorities might now make provision for all forms of sickness, whereas in the past they were only responsible for infectious diseases. The possibilities of the future were further enlarged by the provision that local authorities might recover reasonable charges in respect of treatment from persons who had been maintained in any institution, except in regard to persons receiving treatment for infectious disease. In framing schemes local authorities would require to consider not only the needs of their own area, but the matter of combining with neighbouring areas, especially in regard to institutions for special forms of treatment, such as hospitals for surgical tuberculosis, sanatoriums, and convalescent homes. Areas of administration under the new Act were greatly enlarged, but there would still be a need for joint action between counties and burghs, and such action, when it was desirable, would greatly save unnecessary expense.

Rheumatic Clinic for Edinburgh.

The Public Health Committee of Edinburgh Town Council, at a meeting on December 17th, 1929, decided to recommend the formation of a clinic for rheumatism, following upon a report by Dr. William Robertson, medical officer of health for the city. The report recommends that a system of notification for cases of rheumatism should be adopted with the view of securing an approximate idea of the numbers of persons under 16 years of age suffering in this manner, and of the extent to which they are affected. The report states that rheumatism is much commoner among the young population than was formerly supposed, and that serious heart involvement is frequently discovered among children showing unaccountable indisposition of long duration. The incapacitating effect of this condition is evidenced by the fact that £2,000,000 is paid out to insured persons as sick benefit in a year, so that early recognition of rheumatism might be regarded as directed towards the prevention of serious disability. It is proposed that the notification should be voluntary, and that a fee of 2s. 6d. should be paid for each case of rheumatism in a person under the age of 16 notified to the medical officer of health. The term is understood to include chorea, "growing pains," and pains in the joints, accompanied by raised temperature, as well as definite cases of rheumatic fever. The information to be supplied will include an opinion as to whether hospital or other special treatment is desirable. It is considered that this will give a good idea of the possible demands that may in future be made on the local authority for rest treatment in an institution. As an adjunct to notification it is proposed that a weekly clinic should be held, where appropriate advice about future care will be given to patients referred by their medical attendants.

Ireland.

Medical Benefits in Northern Ireland.

In reply to a resolution from the Armagh board of guardians about the inclusion of medical benefits for Northern Ireland, the Right Hon. J. M. Andrews, Minister of Labour, stated that while in certain areas in Northern Ireland there was little, if any, discontent with the existing dispensary system, the pauper taint was admittedly objectionable, and in many areas the working classes did not feel sufficient confidence in the medical services at their disposal. There were, moreover, other considerations which had to be taken into account in determining the future development of the medical services. In the first place, Northern Ireland was being urged by the Imperial Government to enable it to ratify conventions drawn up by the International Labour Office at Geneva in 1927. These conventions required the subscribing countries to provide medical benefit for workers, including agricultural workers, on an insurance basis, and had already been ratified, or were in process of ratification, by fifteen other countries. Up to the present, owing to the absence of medical benefits in Northern Ireland, the Imperial Government had been unable to do so, and it had been much embarrassed through not being able to fall into line with other countries in the matter of sickness insurance, while seeking to secure that these countries would raise their social standards to the British level in other directions. It was unwise to resist the pressure being exercised by the Imperial Government to adopt the British standards of medical services for insured workers. A further matter which gave him grave concern was the amount of sickness amongst insured persons; during 1928 the average expenditure per person on sickness and disablement benefits in Northern Ireland was £1 14s.; in England and Wales £1 1s. 6d.; and in Scotland £1 0s. 1d. Where insured persons were members of societies which operated in Great Britain as well as in Northern Ireland, the payment of these benefits had entailed loss on the British members, and had made the societies (who attributed the present position in large measure to the absence of medical benefits in Northern Ireland) very restless. Unless some improvement could be effected in the near future in the rate of sickness amongst Northern Ireland members the international societies would cease to operate in Northern Ireland. If, through the dissociation of Northern Ireland from Great Britain in the insurance scheme, the expenditure on sickness and disablement benefits in recent years had to be met out of income in Northern Ireland, the ordinary weekly contribution would have to be raised by 3d. A lesser cost than this would secure the proposed scheme of medical benefits, with all the advantages it contained. Should a system of medical benefits be introduced there would be some modification of the dispensary system and consequent curtailment of cost.

The Ulster Branch of the British Medical Association has appointed, at the request of the Ministry of Labour, an advisory committee representative of the profession, which is to act in a consultative capacity to the Ministry. Arising out of the extension of medical benefits, it is proposed to reduce the salary of the dispensary doctors, on the ground that a number of their patients are insured persons, and will be treated in future under the medical benefits scheme. This proposal has caused considerable anxiety amongst Poor Law medical officers, as they say that 90 per cent. of their work is among the wives and children of the insured and destitute, and that this work will continue under the medical benefits scheme.

Promotion in Mental Hospitals.

A deputation from the committee of management of the Clonmel Mental Hospital waited recently on the Minister for Local Government and Public Health, in Dublin, to discuss the method of filling the vacancy which has arisen in the office of resident medical superintendent, owing to the death of Dr. Bagenal Harvey. The deputation stated that it was the unanimous desire of the committee that they should be allowed to promote Dr. Fitzgerald, who had been for many years assistant resident medical officer in the Clonmel Mental Hospital. The deputation was convinced that this was a case in which the Minister should not insist on the appointment being made on the recommendation of the Local Appointments Commission. The Minister, in reply to the deputation, said he did not take the view that the mere fact that a man happened to be an assistant in a mental hospital when a vacancy occurred gave him an unquestionable right to succeed to the higher post. Experience and local knowledge should properly count, but there were other factors of importance that must be considered. The unanimous recommendation of the Poor Law Commission, that these posts should be filled on the recommendation of the Local Appointments Commissioners, was on record, and reflected what was the best opinion on the subject. The committee

was asking him to ignore the recommendations of the Commission. It was clearly in the interests of the whole medical service of the mental hospitals that there should be a selection free from all local influences. The committee might find it difficult to take that view, but it was the intention of the Oireachtas that certain posts should be filled only on the recommendation of an impartial tribunal, removed from local, political, and personal influences. This was clearly one of the posts in the filling of which the local authority should have the assistance of an expert advisory body. Experience had shown that every committee of management had a natural bias towards the man on the spot, and the practice that had grown up of excluding all outside candidates, no matter how well qualified, had had the effect of keeping capable men for a lifetime in subordinate positions, while juniors, with the minimum qualifications in point of service, had been promoted. Such a system was bound to be detrimental in its effects, and could not be defended on any reasonable grounds. It was essential that the whole mental hospital medical service should know beyond doubt that the department stood for the free flow of promotion, so that the best qualified men would have the way opened to them, and that appointments would only be made after impartial selection. With regard to the question of salary to be paid to the new resident medical superintendent, the Minister did not think it wise, as a matter of policy, to reduce the emoluments to a point at which these posts would cease to be attractive. They must offer an inducement for young men of talent to enter the service. A compromise was reached which, it was thought, would be acceptable to the committee.

Death Following Tonsillectomy.

At an inquest held recently at Ballymena, Dr. John Armstrong made a statement about the risks attending the too early discharge from hospital of children who have undergone an operation for tonsils and adenoids. The inquest concerned a child aged 6 years 11 months, who had been admitted to the Waveney Hospital on October 2nd, 1929, and, following an operation for chronically enlarged tonsils, had died suddenly on October 3rd, at his parents' home. Dr. Armstrong said that he had invited the inquest, after consultation with the medical officer of the Waveney Hospital, because they thought that owing to the frequency with which the operation was being performed the general public was inclined to take too light a view of the dangers that might be associated with it. At the last Annual Meeting of the British Medical Association, the Laryngological Section had passed a resolution that all children who had been operated on for tonsils or adenoids should be kept in hospital for at least forty-eight hours (*British Medical Journal*, August 17th, 1929, p. 303). Moreover, so many parents failed to carry out the directions they received about the preparation of the children, that hospital authorities preferred, for the children's own safety, to admit them twenty-four hours before the operation. After the operation the children required careful attention and skilled nursing. All of them swallowed a certain amount of blood, and if, as sometimes happened, they vomited before the effects of the anaesthetic had passed, the vomited material might get down into the trachea and choke them; only by close observation could such a danger be averted. Dr. Armstrong said that he wished to make these facts public, so that parents might know that an operation for the removal of tonsils and adenoids was not regarded by the medical profession as a trivial matter. It was probable that operations for tonsils and adenoids would be performed more frequently in the future than they had been in the past. With reference to the deceased child, Dr. Armstrong pointed out that the matron had advised the parents to let him stay in hospital until the next day, but they removed him on their own responsibility. Hospital authorities could not keep children if their parents wanted to take them out. A hospital was not like a lunatic asylum or a gaol; parents could take their children out at any time they liked, and neither the doctor nor the matron could prevent them. They could only advise them to let the children stay.

England and Wales.

Health Administration in London.

THE London County Council is rapidly getting in order the arrangements for the new duties which devolve upon it by reason of the Local Government Act. Details of the Central Public Health Committee have already been published (November 23rd, 1929, p. 980). The council has since decided to set up a general hospitals subcommittee consisting of twenty-two members, at least eight of whom shall be members of the Central Committee; a special hospitals subcommittee, constituted in almost the same manner; general hospitals (area) subcommittees, one for each of the five hospital areas of the county; general hospitals (visiting) subcommittees, one for each general hospital, or, if convenient, one for two or more hospitals; special hospitals (sectional) subcommittees, one for infectious diseases hospitals, a second for tuberculosis hospitals, and a third for children's hospitals; and special hospitals (visiting) subcommittees. There will also be a staff subcommittee of eight members, four to be members of the Central Committee; a planning and development subcommittee, an ambulance subcommittee, and a public health subcommittee, the last to deal with the matters which have hitherto come within the province of the existing Public Health Committee, which will shortly be absorbed in the larger body.

The council has also been considering certain amendments to its standing orders made necessary by the new administrative scheme. These relate particularly to the duties of the medical officer of health to the council, which have been considerably widened. His new duties are set out in many clauses of the amended standing order. Among other matters it is laid down that he shall advise on all questions relating to the maintenance and treatment of the sick in hospital; the classification, provision, maintenance, and management of hospitals, and arrangements for their visitation and inspection, as well as consultation and co-operation with voluntary and other hospitals serving the county. He is to be responsible for the administration of all hospitals maintained or managed by the council (other than mental hospitals), for the administration of the council's powers under a large number of Acts dealing with health matters, for local medical services, the conduct of the business of the hospital visiting subcommittees, and for "securing that hospital treatment is afforded to any person entitled thereto, and that the provisions of the law, including all rules, orders, and regulations of the Ministry of Health in relation to hospital treatment, are duly carried out." The personal assistant to the medical officer of health, who has hitherto held the rank of first-class assistant, is to have the higher status of senior assistant, with a special allowance of £112 a year. A new principal assistant medical officer is to be appointed in the Poor Law division of the public health department at a basic salary of £800, rising by increments of £50 to £1,000 a year. (The actual figures, with bonus adjusted to the cost of living, are £995 and £1,205 respectively.) The position of medical consultant (small-pox), vacant by the death of Dr. Wanklyn, is not to be filled at present; temporary arrangements have been made with the Metropolitan Asylums Board for the services of a rota of small-pox experts on the staff of the Board to carry out the diagnostic work.

Queen's Hospital, Sidcup, up to the present used by the Ministry of Pensions as a general hospital, is to be acquired by the London County Council in connexion with the new duties which will devolve upon the council under the Local Government Act. It is intended that this institution, which comprises an estate ninety-three acres in extent, shall form the nucleus of a convalescent home for patients who have been treated in the hospitals which are being transferred to the council, and it will also be used for "decanting" purposes in connexion with the removal of patients from transferred hospitals when alterations are being carried out. The hospital is designed to afford accommodation for 690 beds. The council has also accepted, as a gift from the United Services Fund,

Heatherwood Hospital, Ascot. This hospital, which was opened in 1922, consists of three ward pavilions to accommodate 136 children's beds, a treatment block with x-ray and artificial light departments, and isolation and administration blocks. The hospital was designed for the treatment of children suffering from surgical tuberculosis, and it has also been used for the treatment of other orthopaedic cases. The council of management of the United Services Fund realizes that in course of time the supply of patients to this hospital from various parts of Great Britain will probably cease, owing to the growing provision for the treatment of such cases in their own areas. Moreover, the fund will itself cease to exist in about eight years' time, and the council of management, having spent upwards of £200,000 on the building and equipment, is naturally anxious to ensure that it shall continue to be fully utilized. It has been arranged that the council shall undertake to be responsible for the maintenance of the hospital on the cessation of the United Services Fund, the council in the meantime taking an additional number of beds (up to eighty), that the hospital shall continue to be used for the treatment of children of ex-service men in London suffering from orthopaedic conditions, and that the staff shall be taken over. The council has expressed its sense of the generosity of the offer by the council of management of the fund.

Public Abattoirs.

On the motion of Dr. Stella Churchill, the London County Council has again been considering the question of public abattoirs, and has sought information from the authorities of the more important and representative towns of Great Britain where public abattoirs are provided. In London there are just over one hundred private slaughterhouses—a declining number, for there were 1,500 such places in 1873, and nearly 500 in 1897—and, in addition, the large public abattoir provided by the City Corporation at the Metropolitan Cattle Market, Islington, where three times as many animals are slaughtered weekly as at all the private slaughterhouses combined. From the point of view of public health there are important considerations which can be urged in favour of public abattoirs, the principal being that the inspection of animals, both ante mortem and post mortem, is more efficient. To be entirely effective, however, all the private slaughterhouses in the area should be closed, and power to do this has been secured by some authorities, but, even so, there is nothing to prevent dealers in doubtful meat from removing to some rural area where inspection is not so stringent. The Ministry of Agriculture is about to introduce experimentally in London and Birmingham a scheme for the grading and marking of home-killed beef, and if the scheme, as is anticipated, is confined to animals slaughtered in public abattoirs and in one or two of the largest private slaughterhouses, it is probable that the smaller private slaughterhouses, already greatly diminished, will disappear. Conditions are also changing in the meat trade in consequence of the development of the science of refrigeration; nearly three-fourths of the meat delivered at Smithfield during recent years has been American or colonial. Other considerations which favour public abattoirs, such as the better prevention of cruelty, are, the council believes, effectively met even now by its own by-laws and regulations. Therefore the council has come to the conclusion that while the problem of improving the conditions under which meat is produced was undoubtedly important thirty or more years ago, it is solving itself by the passage of time. The public abattoir at Islington is capable of dealing with the needs of the county of London, and is to be enlarged and modernized, and the council does not consider it necessary to take action in the further provision of public abattoirs for London.

Radiological Aspects of Tuberculosis.

The Joint Tuberculosis Council has arranged for a post-graduate course to be held in the radiological department of the Brompton Hospital for Consumption and Diseases of the Chest, from January 27th to February 2nd, under the supervision of Dr. Stanley Melville. The classes will be limited to twenty-five members, and arrangements will be made at the first meeting on January 27th, at 2 p.m., to form small groups for daily practical study in the department, and for visits to the wards and out-patients. A detailed programme will be sent to members of the course after enrolling. Lectures will be delivered on the x-ray diagnosis of pulmonary tuberculosis; technique; bronchiectasis and lung abscess; intrathoracic new growths; the surgical aspect of pulmonary tuberculosis; and dental radiology. Instruction will be given on screening and dark-room procedures, diagnosis, and reporting. Films will be exhibited and discussed, and it is hoped to demonstrate the technique of lipiodol injection. The approval of the Ministry of Health has been obtained for this course; the fee for attendance is three guineas. Further information may be obtained from Dr. William Brand at the offices of the Joint Tuberculosis Council, Tavistock House North, W.C.1.

Correspondence.

GASTRIC AND DUODENAL ULCERS.

SIR,—There are many points in the "Collective Investigation" concerning gastric and duodenal ulcers[1] which raise matters of great interest. Only those who have undertaken similar work can realize the heavy labour, or appraise the high value, of such efforts as that which Dr. Luff has so successfully undertaken. There is much in his report worthy of discussion.

The chief criticism I would venture to offer on Part I is that it is not enough merely to record such events as "Pain or other discomfort after food" in Table VIII, or "secondary haemorrhage" in Table XX. The true explanation of cases suffering from such disabilities is that ulceration is still present; either there is revival of activity in an old ulcer, or a new ulcer has formed in the duodenum, in the stomach, or, as is most probable, near the anastomosis. The number of gastro-jejunal ulcers is therefore understated; though the percentage given—2.8—is already rather high. The mortality of operations—5 per cent.—is also excessive, and does not represent the standard of modern practice in competent hands. "Shock" after operation for duodenal ulcer, of which 11 patients died, is easily avoidable, and indicates less than adequate preparation of the patient for operation, needless prolixity or exposure during operation, or insufficient care afterwards. If, as your leading article suggests, there is likely to be a "bogey score" for surgeons, I would suggest that a mortality of 5 per cent. does not so much correspond to the golfing skill of a Gillies or a Tweddell, as to the meandering futilities of a Moynihan, with a sorrowful handicap in double figures.

In the "After-History of Gastro-enterostomy," Part II, page 1125, a long report deals with "pyloric ulcers." What exactly is meant by "pyloric ulcers"? It is quite certain that ulcers at the pylorus, or in the pyloric canal, so close to the pylorus that they could not be said to be elsewhere, are extremely rare. My own figures, in numbers greatly exceeding the total examined in this collective investigation, show that "pyloric" ulcers form about 1 per cent. of all peptic ulcers requiring surgical treatment. Ulcers proximal to the pylorus are in the stomach and should therefore be called "gastric." Of the total number of gastric ulcers operated on by me less than 5 per cent. were within 1½ inches of the pylorus. Ulcers distal to the pylorus are "duodenal," and should be so called.

The 454 "pyloric ulcers" dealt with in this investigation were clearly not "pyloric" in the strict sense. Were they, then, gastric or duodenal? References to Tables VI and VII (p. 1125) are here relevant. "Pyloric obstruction" alone was shown in 38 per cent. of the cases, whereas in Part I (p. 1074) pyloric obstruction was found in only 17.1 per cent. of the cases of duodenal ulcer. "Pyloric obstruction" in the very great majority of instances I have seen was in fact *duodenal* obstruction. In few cases was the obstruction in the pyloric canal; and

[1] *British Medical Journal*, December 7th, 1929, p. 1074; December 14th, p. 1125.

n still fewer was it exactly at the pylorus. There is very rarely a difficulty in discovering exactly where a constricting ulcer lies. In Table VII the results of test meals are stated: hyperchlorhydria was present in 80.5 per cent.. a close approximation to the conditions in duodenal ulcer, and remote from those in any type of gastric ulcer. Do not these two pieces of evidence clearly indicate that most of the cases of "pyloric" were in truth cases of "duodenal" ulceration? The fact that throughout the long series no case of carcinoma developed at the site of an ulcer is corroborative of this view.

May I be allowed to offer a welcome and my tribute to the best book ever written in any language upon the subject of gastric and duodenal ulcer? The work of Hurst and Stewart is worthy of the finest traditions of British medicine.—I am, etc.,

London, W.1, Dec. 27th, 1929. MOYNIHAN.

THE SUN CURE AND THE WORK CURE IN SURGICAL TUBERCULOSIS.

SIR,—The paper by Dr. Auguste Rollier, and your editorial note in the *Journal* of December 28th, 1929 (pp. 1206, 1209), remind me of two very profitable and pleasant, if strenuous, days spent at Dr. Rollier's clinics at Leysin in September last.

Up to that time I had not realized the full effect upon surgical tuberculosis of a combination of high altitude, pure air, sunshine, simple orthopaedic methods, and suitable employment for the patients. One was struck at the outset by the cheerful optimism displayed by patients, nurses, and doctors, and the pervading air of good fellowship in every clinic visited. I was greatly impressed by the work accomplished and the results of treatment. It was a revelation to see the splendid muscular development in patients who had been bed-ridden for months, recalling the appearance of athletes who had been continuously exercising their muscles. Whether Dr. Rollier's explanation is correct or not, the fact remains that high muscular development in every visible part of the body is a striking feature in his cases.

The absence of the spinal jacket and the favourable course taken by cases of spinal caries without that support gives one food for thought, and suggests a revision of our methods of treating tuberculosis of the spine.

The series of cases shown of joint tuberculosis with what seemed to be hopeless degeneration of the joint structures, in which, after treatment, apparent regeneration of the joint with restored movements could be demonstrated by *x* rays and physical examination of the patient, completely upset my preconceived ideas on the prognosis in this class of case, and Dr. Rollier's views that "the ankle is of all joints, with the one exception of the wrist, the most favourable from the point of view of curability," are certainly not those upon which I was brought up. If I had not seen cases proving his contention I should hardly have been able to accept his statement.

Altogether, I was greatly instructed and stimulated by my visit, and I cannot speak too highly of the kindness and hospitality of Dr. Rollier, who, notwithstanding the enormous amount of work he has to do, is ever ready to demonstrate his patients and his methods to surgeons interested in this branch of work.—I am, etc.,

ANDREW FULLERTON,
December 29th, 1929. Professor of Surgery, Queen's University, Belfast.

THE IMPORTANCE OF THE FAMILY HISTORY.

SIR,—Without undervaluing the importance of the family history in any branch of medicine, I would affirm that in no branch is it greater than in that of psychiatry. If in this branch the importance of this history is great, no less so is the difficulty of eliciting it. That we should be faced with bona fide lack of knowledge on the part of the relatives of a patient is not surprising. How many of us, as regards knowledge of our forebears, can go further back than our grandparents? Even of our great-uncles and great-aunts most of us, I fancy, know little or nothing. In the rare cases in which a pedigree can be produced it may serve to show what a family has done for the country, or what the country has done for it; or even to prove that it sprang from some predatory Norman or minor Scandinavian king. There may, indeed, be proof of blue blood, but none about the diseases transmitted with it. But when we inquire concerning mental and "nervous" disease in the family forebears of a patient we frequently encounter not only ignorance, but evasion, concealment, and falsehood. I doubt whether in any branch of medicine the family and personal history of a patient is taken with such care, in such detail, as in psychiatry. This is one reason why, at psychiatric out-patients, comparatively few cases can be dealt with in the time allotted. Having been concerned with history-taking over the greater part of thirty-nine years' service in five mental hospitals, including some seven years at out-patients, I should say that the family history obtained has been of value only in exceptional instances. Nevertheless, one has, of course, been expected to give a prognosis in the case, and very often one's opinion has been requested on such difficult points as the choice of a career for the patient (should he recover) or his relatives, the prospects of the latter, the advisability of marriage.

Doubtless, some still talk of Alexander and some of Hercules, but more nowadays of Eugenia—a form of latter-day hero worship by proxy. A brave and inspiring conception. But what are we *doing* nationally to build up a system whereby accurate official data regarding the life-history of the individual, and therefore of the family, shall hereafter be available? Owing to some flaw in the ritual of a contraceptive method a birth, perchance, occurs —*plus* one, puts down the official concerned, as gratified as it is given to officials to be. Who cares? It does not help posterity to mate or live better. Or perhaps it is a death —*minus* one; here posterity might care much if the stated cause of death were reliable. And all in between, the silence of the tomb. The individual's illnesses, with trifling exceptions, are unknown. Whereas, were these compulsorily recorded, along with the *ascertained* cause of death, there would be available, with the passage of time, a set of facts about an individual's ascendants for him to record opposite these in the family pedigree, which should be compulsorily kept. This information would be accessible to authorized persons—thus, officials of the State, members of the family, medical men asked for an opinion, life assurance companies; those who, more rationally than now, will have to deal with criminals and malefactors in general; those who, more rationally than now, contemplate a joint ménage and are willing to give procreation a trial. More interference with liberty! Rather, a sound contribution to the common weal. These health dossiers, one assumes, would be kept at the Ministry of Health in London, and at its branches in the chief cities. A gigantic mass of *paperasse*, truly; but what of it, when all will be gigantic; when each city terrestrial shall have its subterrestrial and aerial counterparts; when cupboards for skeletons shall be plentiful and pigeon-holes no longer at a premium?—I am, etc.,

Hove, Dec. 29th, 1929. EDWIN GOODALL.

POST-OPERATIVE TETANUS.

SIR,—Your annotation in the *Journal* of December 21st, 1929 (p. 1167), on the report on post-operative tetanus by the Scottish Board of Health, is no doubt very interesting and instructive, but the work is a very roundabout and laborious method of arriving at a well-known fact—namely, that the tetanus bacillus will not grow in an aerobic medium. I think that Occam's razor, *entia non sunt multiplicanda praeter necessitatem*, should be diligently applied to all such work. Very many years ago a French surgeon introduced a method of treating aneurysm by the subcutaneous injection of a solution of sterilized gelatin. This had a certain amount of vogue until a few cases of tetanus followed; also tetanus occurred in several cases in America when wounds had been covered up with isinglass plaster. It is well known that gelatin contains calcium, and often the spores of tetanus; the same occasionally occurs in isinglass.

In the *Proceedings of the Royal Society* for 1919[1] there are recorded many experiments by Drs. W. E. Bullock

[1] *Proceedings of the Royal Society*, 1917-18, B xc, 513-523.

(now W. E. Gye) and W. Cramer on the calcium salts as an accessory factor in the production of gas gangrene and tetanus. In a paper on the treatment of pneumonia[2] I showed that injected ionizable salts of calcium contract or destroy the capillaries, and thus deprive the tissues of oxygen. The anaerobic germs will migrate to this chamber deprived of oxygen, and multiply on the dead tissues, whereas aerobic germs cannot exist in such circumstances.

The simple solution of the problem set out is to see that the catgut is sterile, and that there is no anaerobic chamber in which even spores can multiply. Sterilization is often an uncertain process, and as the tetanus bacillus in the presence of oxygen is a harmless saprophyte it is well to see that there is no anaerobic chamber in which it can prey on dead matter. When surgeons used to cauterize an ovarian pedicle there was no risk of introducing even tetanus spores, except when, with unnecessary caution, they supplemented the cautery with the addition of catgut.

There must have been a few unpublished cases of tetanus to have induced the bacteriologists to undertake so much trouble in this matter. It would therefore seem that if surgeons, wise or otherwise, acquire a habit of inadvertently introducing tetanus spores into the abdomen it may be necessary, as a matter of routine, to have a supply of antitetanic serum ready, or to get rid of the anaerobic chamber by filling the peritoneal cavity with oxygen or filtered air. It is also well to remember that there are many other anaerobic germs for which we have got no antiserum.—I am, etc.,

Hindhead, Dec. 29th, 1929. JAMES BARR.

TRAINING OF THE UROLOGIST.

SIR,—I have read with great interest your leading article on the above subject (December 21st, 1929, p. 1165), and while I agree in the main with your panegyric of some of the American urological teaching centres, I feel that you have been unintentionally unjust to our English institutions. You state that "the English school of urology is young." May I point out that St. Peter's Hospital for Stone and other Diseases of the Urinary Organs was founded in 1860, and for almost seventy years has been engaged in teaching urology. If one excludes the special stone hospitals founded in the eighteenth century which had only a brief existence, St. Peter's Hospital was the first and for many years the only hospital in the world entirely devoted to urology. The other great teaching centres, such as the clinic at the Necker in Paris, are special departments of general hospitals. I feel that we may justly claim that a certain amount of success has followed our efforts. Important urological posts are held by men who were trained at St. Peter's Hospital, not only in London and the provinces, but in Australia, New Zealand, India, South Africa, Canada, etc. Graduates come to us for instruction from all the London teaching schools, from the provinces, from the British Dependencies, from most European countries, from America, and even from places as remote as Korea and Chili.

The teaching of urology presents difficulties which are not met with in other specialties. A student cannot injure a patient with the ophthalmoscope or the laryngoscope, but he may inflict irreparable damage with the cystoscope or ureteric catheter. He must show a certain amount of dexterity before he can be allowed to use these instruments. Graduates who come to St. Peter's Hospital for instruction may be divided into three classes. The first come to see the work of the institution, which is open to all graduates but not to undergraduates. They attend the out-patient department, and watch operations on in-patients. The work is demonstrated to them, and they have an opportunity of seeing the condition of the bladder during cystoscopy. They can also examine out-patients, but *they are not allowed to pass any instrument on them.* The second class are the clinical assistants. Fifteen clinical assistants are appointed every six months. They commence by passing bougies on cases of stricture. As soon as they have proved that they are competent, they are taught how to use the cystoscope, and later how to perform intravesical treatment, such as fulguration of bladder growths. This training is invaluable, because if one has learned to place the tip of an electrode accurately on any part of a growth, one will never have any difficulty in passing a ureteric catheter. The third class are the resident surgical officers, of whom there are two, a senior and a junior. Each resident must pass six months in the junior before he can reach the senior position. In fact, the junior position is a training ground to enable him to become competent to undertake the duties of the senior post. In the six months during which each resident acts as senior R.S.O., he assists the surgeons of the hospital at about 200 urological operations, he is responsible for the after-treatment of all these patients, and has to keep their case sheets. In addition, he is allowed to perform operations under the supervision of the surgeon, to catheterize ureters, to perform pyelographies, etc. When he has finished his term of office he is thoroughly grounded in surgical urology.

One may ask if this practical method of teaching is acceptable to post-graduates. I may mention two instances which are typical of many, and may help to give an answer. The first was that of an American who came to Europe for a year's study in urology. He was advised to spend one month at St. Peter's Hospital, and the remainder of the time at the Continental clinics. Instead, he spent eleven months in London, and only one on the Continent. The second was that of an Australian who was one of my clinical assistants a few years ago. He lately returned to England for a further period of study, and mentioned in the course of conversation that he had been strongly recommended to return home via America, as then "he would realize how sound the London teaching was."—I am, etc.,

London, W.1, Dec. 22nd, 1929. J. SWIFT JOLY.

"TENNIS ELBOW."

SIR,—The truth of your editorial comment—"that the etiology of 'tennis elbow' is various, its pathology obscure, and its cure uncertain"—receives additional support from the letters in the *Journal* of December 28th, 1929 (pp. 1213 and 1219), by Mr. Trethowan and Commander Edgar.

While the former says the symptoms are: "pain in the region of the radio-humeral part of the elbow-joint," and "tenderness of the radio-humeral joint, both in front and behind, and especially in front of the tip of the external epicondyle," the latter states that "on examination the pain can be elicited . . . passively, as when the surgeon presses with his thumb immediately above the external condyle of the humerus," and that it is "due to an affection of the extensor group of muscles."

It is evident that these two surgeons cannot be describing the same trouble. Moreover, my own description of the condition would be "pain on pressure over the orbicular ligament, due to injury to that structure," which differs from both the others. As we three may perhaps be described as not unskilled observers, is it not likely that each of us is right, and that each of us has met with the condition he records? I suggest that tennis elbow is due to several pathological conditions, one of which may be traumatic synovitis (Mr. Trethowan), another muscular strain (Commander Edgar), and another ligamentous strain (my own explanation), and that often all three conditions occur in the same elbow. While accepting Mr. Trethowan's view that the trouble is due to a traumatic synovitis, it is difficult to believe that it is limited to the radio-humeral joint, for the joint cavity is directly continuous with the elbow-joint itself.

As regards treatment, it has long been evident to me that some of these cases require rest, some manipulation, some diathermy, and some removal of a septic focus, as mentioned by Commander Edgar. Only experience can decide which will be successful.—I am, etc.,

London, W.1, Dec. 28th, 1929. PAUL BERNARD ROTH.

SIR,—The fact that the discussion on minor injuries of the elbow-joint in the Section of Orthopaedics of the Royal Medical Society[1] *centred round* so-called "tennis elbow" speaks well for the interest of the profession in what Gerald Patterson calls "the best of all games."

[2] *Practitioner*, 1923

[1] *British Medical Journal*, December 14th, 1929, p. 1103

The impression left on your editorial mind by the discussion was that the etiology of tennis elbow is various, its pathology obscure, and its cure uncertain. And yet there is a certain dogmatism in the opinions advanced by the speakers, the only trouble being that each advanced a different dogma, and the chairman, had time permitted, was prepared to disagree with nearly everybody!

Now, Sir, the movements of the arm in tennis are comparatively simple, and the results of these frequently repeated movements, as expressed in pain, should not be so entirely beyond our ken, if they are beyond our skill. *Et ego militari non sine gloria*, for I won a French national championship—now, alas! thirty-three years ago—so I venture to give you the impressions of a veteran who, at the age of 60, can still gladly play a hard five-set single match. May I clear the ground by commenting on some of the remarks made at the discussion.

In the first place, only extreme cases, such, for example, as show the synovial fringes referred to by Mr. Trethowan, come to operation, so I think it is only fair to state that we are more or less in the dark as to the actual pathological condition of the structures involved. Mr. Ogilvie speaks of blood effusion, young connective tissue with or without cells or blood vessels, but we cannot make microscopic examination of these elbow-joints; nor would we if we could. Mr. Ogilvie states the cause clearly: rapid, frequent jerking of the arm into full extension while the fingers are strongly flexed round a large instrument. Every muscle, with its attachment, is therefore involved, and pain may result anywhere between the trunk and the terminal digital joints.

"Tennis arm" would be a better term than "tennis elbow," for the pain is scarcely ever limited (*pace* Mr. Trethowan) to the radio-humeral joint, but can always be elicited by firm pressure over the attachment of the muscles involved. We have not the four cardinal signs of inflammation, but it is surely fair to conclude that pain following the excessive use of groups of muscles implies congestion—congestion of all the parts involved—myositis, synovitis, periostitis, possibly even superficial osteitis, and certainly fibrositis. No doubt, in some very exceptional cases, there may be minute tearing of muscle fibre, and no doubt in all of us there are "circulating toxins."

Mr. Whitchurch Howell's conclusion that tennis elbow was the result of bad tennis has an element of truth in it, but many a finalist at Wimbledon, and many a professional, have suffered from it. His theory of the pinching of a cutaneous nerve lacks proof. I fear Mr. Elmslie would find few players of experience to agree with him that the cause is the "forehand drive in which the hand was supinated and the wrist fully extended." It seems to me a physical impossibility to drive with the hand supinated. Such a grip would inevitably loft the ball.

Undoubtedly manipulation has cured certain cases; I have not seen the actual process, but I have heard, at first hand, of too many to be able to remain sceptical. Mr. Macrae Aitken spoke of successful cases of manipulation which "went flick." But what "went flick"? Had something been displaced? And was it possible to guess what had been displaced? I think a valuable hint, as to treatment, is given by Mr. Elmslie's masseur—to pretend to be doing a lot and to do very little.

My conclusions, then, as regards tennis elbow are: etiology—exaggerated function; pathology—congestion, exudation, and inflammation; and treatment—in bad cases by rest, and in slight cases the patients should carry on.—I am, etc.,

Cannes, France, Dec. 17th. A. A. WARDEN.

SIR,—In the last sentence of his letter Surgeon Commander Edgar mentions what I believe to be the primary cause of "tennis elbow"—namely toxaemia. It is surprising that, in the discussion by the Section of Orthopaedics of the Royal Society of Medicine, but slight mention was made of this as a causal factor. I see no reason for regarding the lesion of tennis elbow as other than localized fibrositis, and as such attributable to the same primary cause as generalized fibrositis, though localized by trauma. There need be no difficulty in reconciling the histological findings of different observers, since at the external epicondyle fibrous tissue exists, in three closely apposed situations: the tendino-fleshy attachment of the extensor muscles of the forearm, the periosteum, and the capsule of the radio-humeral articulation. As at similar sites elsewhere, the incidence of trauma may be on any one of these structures or on a bursa, such as Osgood[1] described, underlying the attachment of the muscles, giving rise to closely similar symptoms. When the capsule is affected the underlying synovial membrane may be expected to be hyperaemic and the synovial fluid increased, as in the cases operated on by Mr. Trethowan (*British Medical Journal*, December 28th, 1929, p. 1218).

Mr. Trethowan dismisses the hypothesis that the lesion is periostitis, though Bergmann[2] stated that he found radiological or histological evidence of it in half of his cases. Mr. Trethowan states also that the suggestion of an affection of the muscle ("chronic muscle strain") is negatived, because similar conditions to tennis elbow do not occur in association with other joints. This is surely not so. Essentially the same symptoms—persistent localized tenderness at a muscle attachment to bone and, on strong contraction of the muscle, pain which sometimes radiates and often suddenly inhibits the contraction—are not uncommon at several other sites—for example, the proximal and distal attachments of the deltoid, the attachments of the erector spinae, and the styloid process of the radius. These are all sites of attachment of muscles liable to prolonged or sudden strain. I suspect that "chronic muscle sprain" is the commonest of the three possible varieties of fibrositis causing tennis elbow. It is significant that in most cases swelling in the region of the epicondyle, which one would expect to be present if periostitis or "synovitis" were the lesion, is absent. Adhesions might form in long-continued cases no matter which of the three varieties was present.

Because the condition usually arises during participation in a sport or occupation involving frequent contraction of the muscles attached to the external epicondyle, the idea of trauma as the sole etiological factor has become firmly established. Trauma seems undoubtedly to play an important part in the causation, but I believe it to be merely the localizing factor. It is notable that gradual rather than sudden onset is the rule. Moreover, the movement with which pain is associated may have been frequently performed for years before the onset. Carter[3] states that cases are on record in which trauma could be definitely excluded, the condition arising, for example, in the left arm of a person decidedly right-handed. Absolute or partial rest for long periods is often singularly ineffective in relieving the symptoms, and treatment by massage and heat, usually beneficial in traumatic lesions, may merely accentuate them. One must conclude that there is some other causal factor, and this I believe to be toxaemia from focal sepsis. The following case illustrates the importance of this factor.

A man, aged 46, developed pain in the region of the left external humeral epicondyle while golfing during October, 1928. The pain was felt only on lifting or gripping an object, with the elbow extended and the forearm pronated or semi-pronated. Numbness of the hypothenar eminence of the same hand was noticed a few weeks later. He had to give up playing golf because of the pain. During the next ten months the symptoms continued unabated in spite of abstinence from golf, a course of galvanization, manipulation of the elbow by a bone-setter, and wearing for the last five months of a splint preventing full extension of the joint. The tip of the external epicondyle was tender on pressure, but there was no swelling. The contour of the elbow was normal, and there was no limitation of movement or pain on forcible passive extension with the forearm pronated and the wrist and fingers flexed. The grip of the left hand was slightly weaker than that of the right, and the maximum circumference of the arm and forearm was half an inch less on the left than on the right side. Sensibility to pin-prick and cotton-wool were diminished over the hypothenar eminence of the left hand. The nerve trunks were not tender, and the muscles of the hand not appreciably wasted. A skiagram of the elbow-joint was normal. Skiagrams of the teeth showed four with apical infection, two of which were crowned.

[1] Osgood, R. B.: *Arch. Surg.*, 1922, iv, 622.
[2] Bergmann, E.: *Arch. f. Ortl. u. Unfall-chir.*, 1924, xxiii, 363.
[3] Carter, B. N.: *Journ. Bone and Joint Surg.*, 1926, vii, No. 3, 558.

The four infected teeth were extracted in October, 1929, and no other treatment was given. Three weeks later the patient reported himself free from pain for the first time for twelve months, and able to play golf without ill effects. There has been no return of pain since, although he is playing golf frequently.

—I am, etc.,

Bournemouth, Dec. 29th, 1929. N. ROSS SMITH, F.R.C.S.

SIR,—The discussion on this subject has thrown considerable light on the pathology of "tennis elbow," but has done little, so far, to aid treatment. I have seen much tennis elbow, both for diagnosis and for treatment, and I am now very firmly convinced that the real cause of it is toxaemia, while the exciting cause is prolonged—or unnatural—strain upon the particular joint. Failure to cure is due to neglect of the general cause—the toxaemia, for until this has been abolished no local treatment can be expected to succeed. Local infections (teeth, tonsils, etc.) must be cleared up, but in my experience the almost universal cause of tennis elbow and allied arthritic or "fibrositic" complaints is intestinal toxaemia. Details of treatment depend upon x-ray findings, but usually they include: (1) diet—insistence upon "live" foods, such as fruits, salads, and whole-meal; avoidance of "putrefiable" foods, especially excess of meat, sugar, and starch; (2) abdominal exercises, to combate constipation; (3) aperients, especially liquid paraffin and salines, to combat stasis; (4) belladonna (in many cases) to relieve intestinal spasm set up by putrefaction of stagnant faeces; and (5) kaylene (colloidal kaolin), to adsorb intestinal toxins. Many an obstinate tennis elbow has yielded promptly to this treatment, which has the great merit of being harmless, since the whole of the kaylene and paraffin are evacuated with the faeces, while the amounts of saline and belladonna needed to complete the action are quite small. Kaylene-ol and kaylene saline are suitable preparations for the treatment.—I am, etc.,

London, W.1, Dec. 27th, 1929. ALFRED C. JORDAN, C.B.E., M.D., M.R.C.P., D.M.R.E.

THE HARVEY MEMORIAL TOWER.

SIR,—I am very glad to see that you are again raising the question of the Harvey Memorial Tower at Hempstead, and are organizing a scheme. I visited the old church last year, the tercentenary of Harvey, and I was saddened to see the utter desolation of the place, reminding one as it does more of the devastated areas in France than of a tiny English hamlet. The photographs you reproduce, though very good, do not convey to my mind, and therefore probably to your readers, the present desolation, for the ruins of the fallen tower remain in the churchyard as they fell, nearly fifty years ago, with one of the three bells buried beneath the debris.

I felt it such a slur on our profession and the nation that the remains of the immortal Harvey should lie in such surroundings that I wrote to the President of the College of Physicians, and suggested a scheme by which the money for the erection of the tower could easily be raised. He replied most sympathetically, and courteously invited me to join his committee, which I regret I was unable to do. I fully agree with Dr. Herbert Spencer that a small subscription from each member of the profession would raise the necessary money, but the difficulty is how to extract these crowns and half-crowns from careless pockets without extensive organization. The suggestion I made to the President was this: the majority of the profession are panel practitioners. Every county and county borough has its Local Medical and Panel Committee, which has command of funds. They each vote per annum a small poundage (¼d.–½d.) for expenses, and a contribution from the balance is generally voted to a medical charity. Let them each vote a fraction of a penny for one quarter of the year and the thing is done.

Last year I addressed the Hants Committee, of which I am vice-chairman, on this subject, and I had a most sympathetic audience. A resolution was passed stating their full sympathy with the project, but requesting a lead from the College Committee. I am sure if the British Medical Association approached the whole of the counties and boroughs in the kingdom in the manner indicated they would, with the minimum of machinery, achieve their object. This scheme would not, of course, prevent non-panel practitioners subscribing in any way they liked to headquarters.—I am, etc.,

Hartley Wintney, Hants, Dec. 20th, 1929. W. BALGARNIE, M.B., F.R.C.S.

*** An article on the Harvey Memorial, by Sir John Rose Bradford, chairman of the committee, will be found at page 23.—ED., *B.M.J.*

THE CAUSE OF NATURAL ABORTION.

SIR,—Your editorial under the above heading (December 14th, 1929, p. 1121) states that the fate of the zygote, the degeneration of which occurs late, "depends on whether the mammal in whose uterus it is embedded produces a litter or only one foetus at a time. In the former, pregnancy proceeds to term, the degenerate zygotes being expelled with the normally developed foetuses; in the latter, natural abortion occurs, rendering possible immediate preparation for fresh gestation."

At term mares not infrequently expel, together with a normal living foal, a degenerated zygote in the form of an egg-shaped or spherical cyst, the thin wall of which is largely composed of osteoid tissue.[1] Such a mole occupies one cornu, the normal foetus developing within the other cornu. Both foal and mole are expelled within the foetal membranes at term. A similar sequel to twin pregnancy occurs occasionally in cows; the degenerate bovine zygote, however, is commonly covered with skin and hair, and, though smaller than the equine mole, appears to be more highly developed. Your contention that the degenerated zygotes are expelled before term is not supported by experience with the mare and cow, both of which commonly produce only one foetus at a time. It would appear that the retention *in situ* of a degenerated zygote is correlated with the possession of a bicornuate uterus, and not, as suggested, with multiparity.—I am, etc.,

Department of Pathology, Royal Veterinary College, N.W.1, Dec. 19th, 1929. TOM HARE.

PROBLEM OF MATERNAL MORTALITY.

SIR,—In a report recently presented by Dr. William Robertson, medical officer of health for Edinburgh, to the Public Health Committee, there appear two or three statements which I think are distinctly unfair to doctors practising midwifery. The report was published in *The Scotsman*, but I do not think that the pages of a lay journal are the place in which I should ventilate my objections. The report says:

> "The maternal mortality rate per thousand births in Edinburgh during the past two years has been 6.6 . . . the causes of death are puerperal sepsis, puerperal haemorrhage, and puerperal eclampsia caused by albuminuria. Of the total of 364 fatalities which occurred during the past eight years, these conditions caused 207 deaths. The somewhat disquieting feature . . . is that sepsis, haemorrhage, and eclampsia can be justifiably classed as preventable conditions."

I consider this last sentence misleading even to medical men. That some cases of sepsis are preventable is admitted. If a general practitioner or nurse is attending a case and has not examined the urine for albumin, and the patient develops eclampsia and dies, we agree that the nurse or doctor has not taken steps which might have prevented that death. That all cases of eclampsia are preventable is contrary to practical experience. That certain cases of puerperal haemorrhage can be avoided is also correct; that all cases of puerperal haemorrhage, even with fatal results, can be avoided is not correct. It is wrong, I think, to give the impression to the lay public that if a patient dies from sepsis, eclampsia, or haemorrhage, the death may justifiably be held as having been preventable in all cases. The responsibility and risk of attending midwifery cases is serious enough without adding this extra burden to the practitioner.

---

[1] Hare, T.: *Vet. Journ.*, 1926, 82, 371.

The report continues:

"Between November 30th, 1928, and October 31st, 1929, there took place 7,389 births in the city. Of these, 1,404 were attended by the Queen's Jubilee Institute of Nurses. The total number of maternal deaths in the city was 53. When the nurses were in attendance the deaths numbered 2. Excluding the cases attended by the Queen's nurses, the maternal death rate for the city was 8.2 per thousand births. The maternal death rate where nurses were in attendance was 1.6 per thousand births."

This again appears to me to be a misleading statement. These 1,404 cases attended by the Queen's Jubilee Institute nurses are really successful cases of the co-operation of doctor and midwife. I employ Queen's nurses very largely in my practice, but all the patients are treated by me, they receive their ante-natal visit from me, I am present at the confinement, and attend during the puerperium, and I make a post-natal examination some eight weeks later. It is unfair, therefore, to state that these cases had a mortality of two when the nurses were in attendance. It ought to read "when the nurses and doctor were in attendance." Dr. Robertson then proceeds to recommend the establishment of ante-natal clinics throughout the city. In the opinion of many of us in Edinburgh this would not contribute to the solution of the problem.

I would venture to make two practical suggestions. Should not every general practitioner be qualified to give ante-natal care? Would Dr. Robertson not broadcast throughout the city that every woman should receive ante-natal care from her own medical attendant or at the maternity hospital? Then the already efficient and well-equipped ante-natal clinic at the maternity hospital would be available as a consultative centre to which practitioners would refer their cases for specialist opinion. The general practitioner, with his practical experience of all branches of medicine, is really the most highly equipped member of the profession to perform ante-natal work.

The next point of constructive criticism I would make is that Dr. Robertson should, for, say, one year, earmark the money he wishes to spend on the establishment of these new ante-natal clinics, as a fund from which he may pay to the practitioners in Edinburgh a fee to cover the cost of professional assistance which they would call in when they had to undertake any operative midwifery. Since acquiring an assistant and partner, I have made it a rule in my own practice to perform no operative midwifery single-handed unless in a case of grave emergency. This has robbed midwifery of half of its difficulties and terror. No provision of sterile equipment or gloves is of value unless the practitioner has the help of a colleague to administer the anaesthetic and is able to carry out his operative work quietly and with due antiseptic and aseptic care. The mere fact of having the second opinion prevents too early interference. I believe the solution of the problem of puerperal sepsis really lies along the lines of providing adequate nursing associated with the general practitioner, who must, however, if he has operative work to perform, have further medical assistance.—I am, etc.,

Edinburgh, Dec. 16th, 1929. A. FRASER LEE, *M.C.*, M.D.

REVOCABLE STERILIZATION OF THE FEMALE.

SIR,—I was much interested in reading Dr. Norman Haire's letter (December 14th, 1929, *p.* 1134), *in which he* says that the insertion of a silver ring into the uterus with the object of providing a contraceptive is harmless.

In September of this year a patient of Dr. Boyd of this town came to see me in order to have an *x*-ray examination of her uterus. She told me that three weeks *previously* she had a ring inserted while she was in London. She was feeling very ill, had a nasty discharge, and was running a temperature. (I enclose a radiogram of the ring *in situ*.) Dr. Boyd and I thought that the ring was responsible for her condition, and accordingly he dilated the cervix and removed the ring. On pulling down the cervix he found a laceration and erosion, and on removing the ring he found the lining membrane of the uterus extremely unhealthy and a purulent discharge coming through the cervix. He thoroughly curetted her and repaired the cervix, and I am glad to say that she made an uninterrupted recovery.

To us it seemed a thoroughly bad principle to introduce a foreign body into the body of a uterus which may or may not have been unhealthy at the time. This is the other side of the question. It would be interesting to know if other practitioners have had any similar experience.—I am, etc.,

Ulverston, Dec. 18th, 1929. RICHARD FAWCITT, M.B., Ch.B.

SIR,—Dr. G. L. Johnson's letter (November 30th, 1929, p. 1031) on temporary sterilization of the female by dislocating the fimbriated ends of the Fallopian tubes has prompted me to record the salient features of an unusual case which came under my notice recently, and which emphatically supports Dr. Norman Haire's objection to the dislocation procedure. The main points in this case were these:

Mrs. I., aged 31 years, and married one year, was operated on in the Royal Samaritan Hospital for Women, Glasgow, by Dr. Gardner on September 12th, 1926. A solid ovarian tumour (found on examination to be a simple fibroma) on the right side was removed, and with it the right Fallopian tube, which was adherent to the ovary and could not readily be separated. Apparently the whole tube was excised. On November 13th, 1927, she was readmitted urgently to the same hospital and diagnosed as a case of ectopic gestation. A tubal pregnancy on the left side was found on laparotomy, and a left salpingectomy was performed. A portion of ovary had to be resected. The diagnosis was confirmed pathologically. Despite the apparent removal of both tubes and an emphatic prognosis as to the impossibility of pregnancy, on October 12th, 1929, Mrs. I. was delivered of a full-time infant.

It is difficult to understand how pregnancy ensued without supposing that a patent portion of the Fallopian tube, however small, had not been removed. It is equally difficult to see how sterility may be obtained simply by dislocating the fimbriated ends of the tubes when it did not ensue even in the above case.

It may not be out of place here to mention the work of Haberlandt,[1] who, since 1919, has been experimenting on the problem of producing temporary sterility in female animals. Subcutaneous transplantation of ovaries from pregnant rabbits and guinea-pigs produced temporary sterility in these. The effect is thought to be brought on by the formation of a hormone in the transplanted corpus luteum, which inhibits follicle maturation. After resorption of the transplanted ovaries the animals became pregnant and gave birth to mature, normally developed, living young. Sterility could be obtained for two to three months. Haberlandt obtained identical results by the daily subcutaneous injection of certain ovarian and placental extracts on the market. He is convinced of a hormonal action in securing temporary sterility in these animals. It is not inconceivable, therefore, that, when we know more of ovarian hormones and when ovarian extracts are really active, Haberlandt's work on animals may be of practical value in producing the temporary or revocable sterilization of women.—I am, etc.,

Glasgow, Dec. 18th, 1929. ALBERT SHARMAN.

CHILD GUIDANCE CLINICS.

SIR,—Dr. Gillespie raises a number of important points, and we agree with his general plea for close liaison between the child guidance clinic and the general hospital. Our two years' practical experience of such a clinic has shown that it is easy, while maintaining independence, to get all necessary help in specialized diagnosis and treatment of physical conditions from certain neighbouring hospitals, though from some others we can get no help at all. We doubt if a general hospital is a suitable centre for a fully established clinic of this sort; its almoner's department works on different lines and with a differently trained staff; the expense is quite beyond the capacity of a voluntary hospital; and an elasticity of method is at all times necessary that is unlikely to be possible in a general hospital. What is needed is a close working arrangement between the two organizations, whereby each provides, quickly and freely, help to the other.

We do not believe that students can usefully be trained in the work of child mental hygiene by attendance at

[1] Haberlandt, L.: Hormonal Sterilization of Female Animals, *Zentralbl. f. Gynäk.*, 1927, li, 1438.

such a clinic. This is not a branch of medicine suitable for pre-graduate study, but should be approached only after a thorough and practical grounding in both general and psychological medicine. For a graduate in his early years to attack the problem of child mental hygiene without the discipline of a lengthy medico-psychological training, and a knowledge of even elementary social problems, would lead to the development of a superficiality in outlook against which this new department of medicine must be safeguarded. It is only by going beyond medicine, into the school and the family, that the proper perspective can be obtained.

The organization of the out-patient department and of the almoner's office of a general hospital are not, as yet, equipped for dealing with problems of this breadth.—We are, etc.,

Child Guidance Clinic, Jews' Free School, Spitalfields, E., Dec. 29th, 1929. NOEL H. M. BURKE. EMANUEL MILLER.

SIR,—I was pleased to see the letter of Dr. Gillespie in the *Journal* of December 28th, 1929 (p. 1219), and I hope that it will attract attention in the right quarters. The indifference of the general hospitals throughout the country to medico-psychology is a very serious matter. Not only does it leave a large proportion of the population without adequate treatment for their neuroses, but, as Dr. Gillespie rightly says, it makes it difficult to see how sufficient men are to be trained in psychological work to meet the ever-growing need.—I am, etc.,

Birmingham, Dec. 30th, 1929. R. MACDONALD LADELL.

"ACTIVATED" FLUORESCEIN IN THE TREATMENT OF CANCER.

SIR,—May I be permitted a final word or two in reply to Dr. Webster's last letter (December 28th, 1929, p. 1220)? I feel that in justice to my colleagues and myself I must enter a protest against the unscientific basis of much of his criticism. To cite an instance: in a former letter he stated that he had tried fluorescein without result; he now admits that this statement was based on a trial with *one* case only, and that a case in which multiple secondary growths were present. Dr. Webster again stresses the point that it is for me to prove that fluorescein, when activated with an appropriate *x*-ray dose, is capable of exerting a more intensive effect on malignant tissues than the same *x*-ray dose alone. I claim that this fact is definitely demonstrated in the series of photographs published in the *Journal of Public Health* for November, 1928, to which I have previously directed attention. It is also of interest, in this connexion, to quote from the report for 1928–29 of the medical superintendent of the North Middlesex Hospital. He states, on page 20, that "recently one remarkable case, which proved refractory to *x*-ray treatment, a large rodent ulcer of the face, healed up in a remarkably short time" as the outcome of the additional use of fluorescein.—I am, etc.,

London, N.W.3, Dec. 29th, 1929. S. MONCKTON COPEMAN.

*** This correspondence is now closed.

MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—A resolution advocating representation of Members on the Council of the Royal College of Surgeons of England has now been passed by large majorities at forty-one annual meetings of the Fellows and Members. The reply to the resolution which was passed at the annual meeting of November 21st last is given in your issue of December 21st, 1929 (p. 1183), in a report of the proceedings at the subsequent meeting of the Council. In that reply the Council points out that no evidence is before them that any considerable number of Members desire a change in the constitution of the corporation. Now the only way to produce substantial evidence is to submit to the Council a widely signed request for consideration of a claim which all must admit to be just. With this object in view a card will shortly be issued to all Members, which we trust, for the honour of the corporation, will meet with a very large response.

At this stage the question whether a Member is personally interested does not arise, for surely the whole body of Members are corporately interested in obtaining a recognition of their desire to be more intimately associated with the conduct of their College. Nor do any questions arise as to what measure of representation should be accorded. All that is needed is an adequate expression of the view that this modification in the constitution of the College should be brought about. In the meanwhile, financial help to meet the expenses of the movement is urgently needed, and I shall be glad to receive subscriptions towards the cost, which we estimate will be about £250.—I am, etc.,

60, Welbeck Street, London, W.1, Dec. 30th, 1929. ERNEST E. WARE, President of the Society of Members.

THE ACETIC ANHYDRIDE TEST IN CEREBRO-SPINAL FLUID.

SIR,—May I put forward three points concerning the Boltz test, in reply to Dr. Grossman's letter in your issue of December 7th, 1929 (p. 1084)?

(1) I can confirm Dr. Herbert's finding that the reaction is due to tryptophane, having come to this conclusion working independently and from a different point of view. (2) The reaction is therefore only an indirect test for an excess of protein, and is positive when applied to cerebro-spinal fluids of high protein content from non-syphilitic cases. (3) In asylum practice the test is probably valuable, as the non-syphilitic insanities are not associated with a high protein content in the cerebro-spinal fluid, but in general hospital practice the test is useless.—I am, etc.,

King's College Hospital, London, Dec. 18th, 1929. C. E. NEWMAN, M.D.

The Services.

DEATHS IN THE SERVICES.

Lieut.-Colonel Arthur William Tuke, Indian Medical Service (retired), died very suddenly, while playing billiards, in the New Club at Cheltenham, on December 7th, 1929. Another medical man was present in the billiard room at the time, but nothing could be done, and he died almost immediately from cerebral haemorrhage. He was the youngest son of the late H. G. Tuke, Esq., barrister-at-law, of Charlton Kings, Cheltenham, and was born on March 30th, 1871. He was educated at Cheltenham College and at St. Thomas's, and took the M.R.C.S. and L.R.C.P.Lond. in 1896; also subsequently the F.R.C.S.I. and the D.P.H. of the Irish Colleges in 1906. Entering the I.M.S. as lieutenant on July 27th, 1899, he became lieutenant-colonel on January 28th, 1919, was placed on the selected list for promotion on March 28th, 1925, and retired on July 27th, 1926. He served with the Aden Boundary Commission in 1903–4, and in Mesopotamia during the great war. After his retirement he settled at Cheltenham, and built a house for himself on Cleeve Hill. He took a great interest in the enlargement and development of the Winchcombe Hospital, of which he was honorary secretary and treasurer. While in India he married Miss Anna Boyd, of a County Cavan family, who is left a widow without children.

Major Robert Sutherland Strachan, R.A.M.C., died suddenly at Cairo on December 10th, 1929. He was educated at Glasgow, where he graduated as M.B. and Ch.B. in 1915, entered the army as lieutenant on June 15th, 1917, and became major after twelve years' service. He served during the latter half of the war of 1914–18.

Major William Egan, D.S.O., O.B.E., R.A.M.C., died on December 11th, 1929, at Kingston, Jamaica. He was educated at University College, Cork, and at the Catholic University in Dublin, and graduated as M.B., Ch.B., and B.A.O. of the Royal University of Ireland in 1904. After filling the post of house-surgeon to the County and City Infirmary, Waterford, he entered the R.A.M.C., attaining the rank of major on January 30th, 1918. He served throughout the war of 1914–18, was mentioned in dispatches in the *London Gazette* of December 24th, 1917, received the D.S.O. on January 1st, 1918, and later the O.B.E.

Obituary.

SIR WILLIAM MILLIGAN, M.D., C.M., LL.D.,

Consulting Aurist and Laryngologist, Manchester Royal Infirmary.

SIR WILLIAM MILLIGAN, whose death we recorded last week, was the third son of the Very Rev. William Milligan, D.D., Professor of Biblical Criticism in the University of Aberdeen, who married Anne Mary, daughter of David Macbeth Moir of Musselburgh. David Moir, under the *nom de plume* of "Delta," was a well-known writer of Scottish stories and of poetry. William Milligan was born on August 24th, 1864, and was educated at Aberdeen University. He qualified in 1886 with the Aberdeen degrees and the diplomas of the Edinburgh colleges, and was awarded honours for his M.D. in 1892. After acting as demonstrator of anatomy at Aberdeen he came south to the Northern Hospital, Liverpool, where he held the posts of house-physician and house-surgeon. Whilst at Liverpool he contracted blood poisoning, and went a couple of sea voyages to recuperate. It was on one of these, it was said, that he met Dr. Pierce, then the aural surgeon of Manchester, who, being impressed with his personality and promise, suggested a partnership, and Dr. Milligan visited the town to see what the prospects were. Scottish medical friends encouraged him, and so he settled there in 1889. Having decided to specialize, he went for a time to Göttingen and Vienna to study the Continental methods of treatment. Aural and nasal surgery was not very efficient then in Manchester, nor in England, and, with the knowledge that he had gained on the Continent, he had his opportunity, which he made the most of. He was soon appointed an honorary surgeon to the Ear Hospital, and in 1899 as aurist and laryngologist to the Royal Infirmary, and it was in the latter post that he became widely known and did his best work. He was also appointed lecturer in the University. He was very neat, skilful, and resourceful, and, when occasion required, bold in his surgery, and a teacher of the first order—clear, instructive, and very attractive to students. He soon got a good practice, which in his later years, when he was so well known, became very large. After being in Manchester about ten years he was invited by Sir William Dalby to join him in practice in London, but there being no hospital post in view Milligan preferred the bird then in his hand. Had he accepted the offer there is no doubt that he would have worthily carried on the Toynbee, Hinton, Dalby traditions of Savile Row.

Always taking interest in the scientific side of his work, he was one-time president of the Manchester Medical, Clinical, and Pathological Societies, and of the Laryngological and the Otological Sections of the Royal Society of Medicine. At the Manchester Meeting of the British Medical Association in 1902 he presided over the Section of Otology, and he had previously held official posts at the Ipswich (1900) and the Bristol (1894) Meetings in his Section. During the war he was consulting surgeon in the North-Western area, with the rank of major R.A.M.C.(T.F.).

He filled his day very fully: up early transacting a good deal of business before leaving for the hospital or nursing home, where he arrived punctually to the minute—9 o'clock; his house-surgeons could rely on this so surely that the anæsthetic would be partly administered before he arrived in his theatre ready for work. Then he would have a light lunch at his rooms and see patients from 1 o'clock for four or more hours. More letters, and then home, and often social engagements in the evening. In spare moments he worked at his hobby of carpentry, making beautifully finished models, such as dolls' houses. He published, along with Dr. Wyatt Wingrave, *A Practical Handbook of the Diseases of the Ear*, and a smaller work on the same subject for students. He wrote the article in Allbutt's *System of Medicine* on "Chronic suppuration of the middle ear and labyrinth," in which he described his own special operations and instruments. In addition, he communicated several papers to the medical journals. He was created Knight Bachelor in the summer of 1914, and awarded the honorary degree of LL.D. by his own Alma Mater in 1927. He was a justice of the peace for Peeblesshire, in which county he had an estate at Polmood.

Milligan was a first-rate business man, and his capacity for money affairs secured for him a place on the board of directors of an important Scottish trust company, of which last year he became chairman. This quality made him a good committeeman, in the chair or out of it. Those who worked with him in appeals for cancer funds were much impressed with his devotion to the work, whether it meant visits to Liverpool, Warrington, or meetings at home. Indeed, he was taken ill for the first time the day after he returned from Liverpool after a committee meeting, when his colleagues travelling with him thought he was not as well as he had always appeared to them to be. He was of a very strong, forceful personality, liking to have his own way, but, on occasions when he could not get it, he accepted defeat with a good grace and bore no resentment. Although far from well, he went to Durham, and again to Sunderland, in November last, to support the cancer campaign in the North, and he kept up his practice and his public activities at home until the day before his final illness.

The foundation of the Manchester and District Radium Institute owes a great deal to his energy and his influence with the late Sir Edward Holt, who found a large sum to establish it. He was its secretary, real business manager, and director of its policy from its foundation. As he had a large practice amongst well-to-do classes he was able to secure subscriptions for the Institute, and later for the campaign in Lancashire, Cheshire, and North Wales for cancer research, organized by the Manchester and Liverpool committees on cancer, and the British Empire Cancer Campaign. He acted as chairman of the Manchester members of the executive committee of this appeal. He was a member of the council of the British Empire Cancer Campaign, and president-elect of the National Health Education Society. No medical man ever attained such a prominent place in the public life of the town as he did. He considered it his duty to do what he could for a city of which he was proud to be a citizen, and, consequently,

he was in great request for presiding at meetings on subjects not always of a medical nature. He was the first medical man to speak from the pulpit of a church on Hospital Sunday, when collections are made for voluntary hospitals of the town. Other members of the profession followed his example, and during the past year the local Branch of the British Medical Association circularized its members asking for volunteers for such charitable work. He could write terse and telling letters, and could also speak convincingly, and the latter he did best when his time was as limited as was the space in the columns of the newspapers. During the general strike he enrolled as a special constable, and his well-known figure was to be seen from time to time directing very efficiently the traffic in the town. He was chairman of the local branch of the National Lifeboat Institution for close on ten years, and worked hard for its centenary bazaar in the town. As a reward for this he was made a life vice-president in 1924—the highest honour that can be awarded to an honorary worker for the cause. Lady Milligan supported him in this work, and was awarded a gold medal for her outstanding service. An unrivalled host, he entertained freely, and many and varied indeed were the guests that enjoyed his choice and generous hospitality.

He was always a Liberal and free trader in politics, held office as chairman, and was an active worker and speaker at meetings in his own division for many years. When the Prime Minister of the day was visiting Manchester in 1918, he was taken ill in the private apartments of the Town Hall. He would not see a doctor, but as Sir William Milligan was attending a member of the Prime Minister's family for an influenzal "throat," he was introduced into the sick room to report, and, being there, the invalid was persuaded to submit to treatment by him for a similar ailment. Subsequently the physician accompanied his patient to London, and, at a later date, to international conferences at Spa and Paris. His political work culminated by his contesting West Salford for the Liberals in 1922. He was in many ways an ideal candidate, a prominent popular and public man in the district, a fluent and convincing speaker with good presence, a tireless worker, and not without financial means; he enjoyed the rough and tumble of the election, but was very disappointed at being at the bottom of the poll in a triangular contest. He did not again contest this or any other constituency.

He married in 1890 Bertha Warden, daughter of James Anderson, founder of the Orient Line of steamships, and leaves one son and one daughter. They mourn the untimely loss of a devoted husband and father, and in this they have the sympathy of innumerable medical friends.

A largely attended public memorial service was held in the Manchester Cathedral on the invitation of the Dean, who conducted it, at which the Lord Mayor, the president of the Chamber of Commerce, and other leaders of civic and commercial life, and representatives of the many hospitals, charities, and institutions with which he had been helpfully associated, were present. The remains were cremated after a private service at the crematorium, and there they remain, at any rate for the present. E. M. B.

Sir JAMES DUNDAS-GRANT (London) writes:

It is difficult to realize that the powerful and attractive figure of William Milligan has been removed from our midst. For many years he commanded the attention of the special societies and sections, and if he had lived would have done so for a good many years to come. This is true not only of the professional side of his life but of the social and public sides as well. The highest titular distinction would probably have fallen to his lot had he been spared, and he would have played his part with efficiency and distinction. His professional relations with Mr. Lloyd George during the war afforded ample evidence of the high esteem in which he was held by that discerning statesman. In return Milligan paid enthusiastic tribute to Mr. Lloyd George's almost uncanny powers of prescience and accurate visualization as displayed during his trying visit to the scenes of military activity. Milligan was firm in his opinions, and stood loyally by the Liberal party in its period of fallen fortune. In private life his sunny brightness made his presence a joy to his family and to his many friends. His wisdom in counsel and his sympathy in times of stress and anxiety made him an invaluable friend. He was more than welcome on occasions of gaiety and relaxation. As a travelling companion he was ideal.

Whatever he undertook he did with his might, and his *might* was very considerable. True of him in his work, this was equally so in his play. His activity in his recreation was seen at its best when he indulged in his hobby of carpentering, in which he was able to turn out work which would compare well with that of the trained artificer. His mental and bodily vigour rendered it indispensable for him to be doing something or making something. Careful and accurate in business matters he was generous to the point of lavishness in his hospitality. He displayed the Scottish character at its best.

A worthy addition to the brilliant body of "sons of the manse," Milligan was actuated by the best motives that the early training in regularity of life, in industry, and in seriousness of purpose could inspire. Though admittedly *propositi tenax* he possessed a fine flexibility of judgement and an adaptability of character that enabled him, without offending, to enforce his views to the advantage of all concerned. It would here be out of place to make the time-honoured quotations from Horace and from Shakespeare. They would indeed be appropriate, but it may be said, without affectation or exaggeration, that he was a great and a good man, much loved and respected during his life, and after his death long to be mourned and remembered.

Mr. HERBERT TILLEY (London) writes:

With the passing of Sir William Milligan, otology and laryngology lose one of their most brilliant exponents and an authority whose reputation was world-wide. Nature had been kind to our colleague, and the tall, alert figure, the well-cut features, combined with a commanding personality, at once arrested attention in any company, and particularly so in the international conferences which he so frequently attended. His public appointments and high professional attainments are known to all who are particularly interested in diseases of the ear, nose, and throat, and his written contributions to those branches of medicine will always rank high in the literature of otology and laryngology. But to those of us who were of his time, he will probably be remembered best for his power of making a clear, judicious, and convincing exposition of any subject to which he had given attention. It always appeared that any opinion he offered was the result of a carefully analysed practical experience, and more often than not his conclusions left one with a feeling that, for the time being, there was nothing more to be said in the matter.

Sir William Milligan possessed a type of wisdom which was invaluable in council, and his loss as chairman of the directors of the *Journal of Laryngology and Otology* will be very difficult to replace. I remember well after one of the annual meetings of the directorate of the above-mentioned journal, the chartered accountant who was present said to me at the close of the meeting, "Well! a large part of my life is spent in attending company meetings, and I don't think I have ever seen or listened to a more efficient and capable chairman—he knows his job from A to Z—would to Heaven we had more like him in the city." For some years Sir William Milligan had been my co-examiner for the M.S. degree in oto-laryngology in the London University, and during the *viva voce* and practical parts of the examination he impressed me with his intimate knowledge of general medicine, and his insistence that such was the essential foundation of special practice. On such occasions he was frequently my guest, and then one became acquainted with his many hobbies and interests outside his professional work. It was during these visits that were revealed a kindness of heart and personal charm which might not have been suspected in the cut and thrust of public debate. Our special department is much poorer for his loss, in that it is improbable that we shall see his like again.

Dr. P. WATSON-WILLIAMS (Bristol) writes:

My friendship with Sir William Milligan dates from the meeting of the British Medical Association at Bristol in 1894, when we were joint secretaries of the Laryngological and Otological Section, and one could not fail to be impressed with the scientific enthusiasm of my genial and debonair colleague. In the midst of his very busy life he was always keenly responsive and "quick in the uptake" to any useful suggestion. When the great war came we realized that the army medical services were ill equipped in regard to the subjects of our specialty, and when, in reply to a letter to Sir Alfred Keogh, Director-General A.M.S., he replied that he would be grateful for information, Milligan, with the writer, was invited to draw up a scheme. This comprised organization of the services of oto-laryngologists at home and at the front, including the special hospital clinics in France which eventually materialized at Havre and at Rouen. The influence of Milligan's vitalizing personality will long be felt, though it is hard to realize that his charm of presence is withdrawn from our midst. So recently as August 5th Milligan wrote, "I go back to Manchester upon August 10th, and intend to start work again at once and hope to attend meetings in London this winter. My main regret at not being at the Manchester Meeting was that it gave me no opportunity of entertaining old friends. I was asked to be President of the Section, but declined because at the time I was not fit to do any spade work." It was like Milligan to refuse the honour of the chair as he could not do the work of organization, yet it must have been a grave disappointment, as the growth and development of the great Manchester clinic has been so very largely due to his scientific work and enthusiastic organization. So eagerly looking forward to the resumption of his professional and other activities, his death truly is a grave loss to our specialty, a great bereavement to his many friends, and grievous sorrow to his wife and family.

Mr. LINDLEY SEWELL, aurist and laryngologist to the Manchester Royal Infirmary, writes:

As the first of a line of aurists to be trained by Sir William Milligan, may I pay a heartfelt, if feeble, tribute to his memory? When Milligan first came to Manchester the only treatment meted out in ear diseases was the use of various "drops" and sometimes the Wilde incision. He introduced the modern surgery of the ear, nose, and throat into this district. This was not done without some opposition, and he had a stiff fight before he overcame the prejudice of the general surgeon and was allotted beds. He was a bold and dexterous surgeon, and preferred the major to the minor operation, and to the more finicking measures which are common in the specialty. Thus, with the exception, of course, of the submucous resection operation on the septum, he did not perform any of the many intranasal operations now so commonly done, especially in Continental clinics. It was a favourite saying of his that there are two big principles in operating —one, to see what you are doing; second, to give good drainage. He was at his best in the radical mastoid operation, and although I have seen operators in almost all the large Continental centres, I never saw his better at this.

Milligan had the energy of two men, and I have rarely seen him tired. Frequently I have had to wait until ten o'clock at night before some matter could be discussed with him, and then he would be found as fresh as paint. He possessed a very clear, logical, and tidy mind, and could, I am sure, have been a very successful business man. His acumen in this line was shown by his success in the many public committees on which he sat during his later years. His very busy practice—and this came very early in life to him—precluded his carrying out any original research on any scale, and I do not think that his bent was in this direction. He had a great executive mind, and could marshal and evaluate the findings of others and apply them to practical purpose. His most outstanding features were his abounding energy, his incapacity of fatigue, and the thoroughness with which he saw through to completion any work which he had begun. He could have made his mark in any line of life. Mr. F. G. Wrigley and myself, his colleagues at the Manchester Royal Infirmary, will sadly miss his ready, kindly, and always valuable advice.

[The photograph reproduced is by Press Portrait Bureau.]

THE LATE Mr. J. SCOTT RIDDELL.

WE are indebted to Dr. THOMAS FRASER, lecturer in clinical medicine, Aberdeen University, and physician to the Aberdeen Royal Infirmary, for the following appreciation:

By the death of John Scott Riddell a forceful and striking personality has been removed from the medical circle of the North-East of Scotland. Though never of powerful physique, he was for long possessed of boundless energy, an acute and active brain, with a quickness of mental action possessed by few. This quality was often disconcerting in conversation from the incisiveness of the repartee which suddenly shot forth.

Riddell was a born teacher, and early in his medical career developed this faculty, not only in the infirmary and university, but also in courses of ambulance instruction, which he initiated and conducted in Aberdeen under the St. John Ambulance Association for many years. A ready speaker, a voracious reader of the best in general literature, and well equipped, therefore, in the language side of teaching, he added to these gifts of lucidity and illustration, combined with a great grasp of essentials and a dogmatic style, which made him an ideal and inspiring teacher. No student attended a lecture or demonstration by Riddell without carrying away something of value to his surgical equipment. He became surgeon in charge of wards at the early age of 34, and for long thereafter occupied the place in the practical surgery of the North-East which was vacated by Sir Alexander Ogston when he resigned his hospital appointment in 1898. Riddell proved no unworthy successor to the celebrated chief whom he had assisted in university and infirmary for seven years. Visits to Continental clinics, especially Germany, had kept him informed of the movement towards aseptic technique, and though it was Henry Gray who brought the completed aseptic system to Aberdeen in 1897, he found Riddell prepared and receptive, and the new system was rapidly adopted in his wards. Few surgeons made more careful or detailed preparation for operations than he did, and this was reflected in the results of his work and the confidence he inspired in the medical and lay public of the area which he served. He was a skilful diagnostician, and the meticulous care with which he investigated his cases led to the rare appearance of the term "exploratory laparotomy" on his operation lists.

Much might be written on his many activities outside the purely surgical sphere, but I feel that it will suffice to refer to his devotion to ambulance work, both civil and military. Ogston was no doubt the stimulator here by his interest in war surgery, which led to his active participation in the Egyptian campaign, and to the formation of a company of the V.M.S.C. in Aberdeen University. Riddell became one of the original band of officers in that company. From that moment his interest in this side of medical work never flagged, until the great war ended and Aberdeen, by ill-considered political action, was deprived of its medical units. When Lord Haldane was considering his great Territorial Force scheme Riddell was commanding the Aberdeen Medical Units with great success. He had keen military instincts, a strong sense of discipline, combined with great powers of organization. His command was in fine fettle and at full strength, and it is known that he was freely consulted by Sir Alfred Keogh, the then Director-General, who was working out the plans for the Territorial Force medical organization. He became the first A.D.M.S. of the Highland Division, while Mackintosh and Lister commanded the Aberdeen ambulances. The success of this combination was reflected later in the war record of the Aberdeen Medical Units, which recruited over 2,000, of whom over 1,600 served in field ambulances. Some degree of disability had already overtaken him before the outbreak of war, and it must have been a keen disappointment that he was unable to undertake the active duties in the field for which his training, experience,

and talents so eminently fitted him. With characteristic courage and determination, however, he undertook, in addition to his surgical duties, the administration of Red Cross work in the wide north-eastern area during the war, and also acted for two years as medical superintendent of the infirmary. The enormous amount of work he carried through then evoked the wonder and admiration of all who knew him and recognized the strain that it must have put on him.

An eminent surgeon, a great teacher, a staunch friend, a "bonny fechter" who left no dubiety about his views, Riddell bequeathes a memory which will live long in the minds of those who were his students or served with him in any of his widespread and public-spirited activities. Though it is ten years since he laid down his teaching appointments, the large attendance at his funeral of present-day students from the University showed how the recognition of his work and worth was being passed on from year to year.

We regret to record the death, on December 10th, 1929, at 28, St. James Square, Bath, of a veteran member of our profession, Dr. DAVID THOMSON. He was born on September 9th, 1844. After studying medicine at the University of Glasgow and in London, he graduated M.D.Glas. in 1865, and C.M. in 1868. He was for many years in general practice at Luton, and became a member of the staff of the Bute Hospital in that town, being appointed consulting surgeon on retirement from active work. He had long served as a medical officer in the old Volunteer Force, in which he attained the rank of colonel R.A.M.C.(V.), and was awarded the Volunteer Decoration. After relinquishing practice Dr. David Thomson lived in South Africa for a time; he then returned to England to make his home at Bath, and during the war he worked at the local war hospital. He was the father of Dr. F. G. Thomson, President of the British Medical Association in 1925–26, and of Dr. H. Campbell Thomson, consulting physician for nervous diseases to the Middlesex Hospital.

We regret to record the death, at the age of 70, of Dr. J. HERBERT HACKING, which took place at his home at Wilmslow, Cheshire, on November 19th, 1929, after an illness which compelled his retirement from practice eighteen months ago. A Manchester man, he received his medical education at Owens College and the Royal Infirmary, and obtained the diplomas M.R.C.S., L.R.C.P. in 1885. Two years later, after holding the post of house-surgeon at the Manchester Royal Infirmary, he started practice at Wilmslow. For many years Dr. Hacking served as surgeon with the Auxiliary Forces, and retired with the rank of surgeon lieutenant-colonel and the Volunteer Decoration. During the war he was appointed commandant and medical officer in charge of the Wilmslow and Styal Auxiliary Red Cross Hospital. For over twenty years he was lecturer to the local branch of the St. John Ambulance Association, and he was made an Officer of the Order of St. John of Jerusalem in England. A colleague writes: Dr. Hacking frequently attended divisional meetings of the British Medical Association; of a most sociable disposition, he liked to meet his fellows for a game of billiards and at professional gatherings. He was a keen sportsman, and usually took a shooting holiday in Anglesea. His upright character, kindliness, and quiet humour won the esteem and affection of his many friends. A devoted churchman, he held the office of churchwarden for many years.

The following well-known foreign medical men have recently died: Dr. PAUL LECÈNE, professor of surgery in the Paris faculty of medicine, surgeon to the Hôpital St. Louis, and officer of the Legion of Honour; Dr. GÉLIS, honorary professor of the Montpellier faculty of medicine, aged 72; Professor VICTOR VASSILIEVITCH, an eminent Russian cardiologist and director of a central institute for study of professional diseases, aged 54, of angina pectoris; Professor OTTO KUFFLER, a Berlin ophthalmologist and editor of *Zentralblatt für die gesamte Ophthalmologie*, aged 54; and Professor R. SALZWEDEL, formerly general in the service of military medicine in Berlin, aged 72.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT now stands adjourned till January 21st. On December 23rd the House of Commons discussed Egypt, and on December 24th financial policy.

In the House of Lords, on December 20th, the Royal Assent was given to the Highlands and Islands (Medical Service) Additional Grant Bill. The Royal Assent was also signified to the Expiring Laws Continuance Bill.

On December 23rd the Mental Treatment Bill, which has passed the House of Lords, was read a first time in the House of Commons.

The Home Secretary presented to the House of Commons, on December 24th, a memorandum on "factors which have operated in the past and those operating now to determine the distribution of women in industry."

The Midwifery, Maternity, and Child Welfare Bill, introduced by Mr. Alpass, is formally entered for second reading in the House of Commons on January 22nd, but is stated to be withdrawn.

Road Traffic Bill.

Debate on Motoring Casualties and Hospitals.

In committee on the Road Traffic Bill, on December 18th, the House of Lords considered Clause 34, which requires every motorist to take out a third-party insurance, or some equivalent against liability in respect of the death of, or bodily injury to, any person caused by, or arising out of, the use of the motor. Lord LUKE moved to add words providing that any policy issued under this clause should also "insure to any hospital treating any such bodily injury payment of the cost of such treatment up to a maximum payment of £25. He said that during 1927 the hospitals of the provinces treated, at a cost of £230,000, 26,000 in-patients and 39,000 out-patients as the result of motor accidents. From insurance offices and the patients only £26,000 was recovered. The few hospitals which were near the trunk roads received these cases in excess, in beds which had been provided for local needs. The maximum of £25 which he proposed was at the rate of £1 a week for six weeks. Usually the average weekly cost would not be greater than £4. If such a risk were added to anyone's policy the annual cost would only be about one or two shillings. Hospitals should have this first charge on the insurance.

Viscount KNUTSFORD said this amendment would not deal with all accident cases brought to hospitals through motor accidents but only with those where the driver was insured against third party risks and the accident was due to his negligence. If a man who was injured in an accident was taken to a nursing home and treated by a doctor the insurer had to pay the expenses as a liability in consequence of his negligence, whereas if that same patient was taken to a hospital the insurer was not liable, because the hospital had no legal liability to recover the costs incurred by it. Hospitals made no complaint of the burden. They were there to help the injured. He himself had been run over and nearly killed by a motor trolley. He was taken to a hospital. There he was not asked how much he would pay to be treated, and the man who ran him over paid nothing for the treatment at the hospital. A hospital might have to spend much more than £25 *in treating a patient.*

Lord SOMERLEYTON said the Voluntary Hospitals Commission had last year unanimously recommended legislation on this point.

Lord BERTIE OF THAME moved an amendment to Lord Luke's amendment. He desired to provide that the payment by the insurance company might be "or to any surgeon or medical practitioner rendering first aid." Doctors who lived near the scenes of frequent accidents complained that they treated persons who not only did not pay, but did not return articles which were lent to them.

Lord STANLEY OF ALDERLY said there was a distinction between a hospital and a medical practitioner. There was a common law remedy for the injured person to sue the motorist for damages and the cost of medical treatment. If the injured person were taken to a medical practitioner the claim of that practitioner would be a proper claim against the insurance company. Hospitals were voluntary associations, and as such could not institute an action or make a legal claim against the injured person or the person causing the injury.

Lord ATKIN said he knew of no insurance policy where the company promised, not to insure the motorist against liability, but to pay some third person direct for something for which the motorist was not liable. That interfered with the principle of insurance, which was the principle of indemnity. His opinion was that in many cases hospitals were in a position to make a charge against the patients. They had private wards, and charged for them. Many cottage hospitals charged for every bed. There was no reason why any hospital should not say, "We make a charge for any party who comes to us who is injured in a motor accident and remit the charge if, in fact, it is not covered by

insurance. If there were difficulties the real remedy would be to provide that any person injured by the negligence of a motorist should be entitled, as part of his damages, to a sum, not exceeding £25, which he had paid, whether legally liable or not, to a hospital for attention to his injuries.

Lord DANESFORT said that these new patients from afar had immensely increased the difficulties of voluntary hospitals. The new liabilities caused by taking patients who had been injured by motors had put York Hospital in a serious position. The point raised by Lord Atkin was only a technical one.

Lord EBBISHAM said that last year four small hospitals in Surrey had spent £2,000 on patients injured by motors but residing outside the locality. He asked whether Earl Russell, who was in charge of the bill, would, if he had to refuse the amendment, consider the possibility of supporting the hospitals in recovering stated charges for attendance from patients resident outside the area of the hospital. There was a parallel to this in Acts dealing with fire brigades.

Earl RUSSELL said he was aware of the grievance of the hospitals, which had grown in the last two or three years. The comparatively small local hospital had reason to complain, but the amendment proposed by Lord Luke was not the way to remedy that grievance. It was inconsistent with the general scheme of insurance in the bill, and it would not cover all cases. There seemed a unanimous feeling that something should be done, and he suggested that a separate clause should be drafted to provide for the insurance of all motorists, say, by a levy of 5s. on every person who took out a licence. There would be no obligation to pass that 5s. to an insurance company; it could be paid to a central fund, administered for the benefit of the hospitals. He invited Lord Knutsford to confer with him and the Government's advisers before the report stage to see if a separate clause could be drafted. There was the difficulty about hospitals not having a legal claim. They would have to consider if hospitals could obtain a legal claim by altering their rules, or whether the clause should give them a legal claim. He wished to give one word of warning—that if once a hospital which was voluntary began receiving contributions from any source in a manner which was not voluntary it was altering its character in a way which might ultimately expose it to some form of public management.

On behalf of the British Hospitals Association Lord BERKENHEAD asked Earl Russell to approach the question from the point of view of the amendment, and not by way of a levy on motorists of 5s. a head, to raise a fund. They required to put hospitals in the position of the ordinary nursing home.

Lord CECIL OF CHELWOOD said that one very serious grievance in country districts was that hospitals provided by the locality were, in fact, utilized by motorists. That grievance would not be dealt with in the manner the House was approaching the question. Country doctors could tell pitiful stories of how the poor were unable to get hospital treatment because the hospitals were filled up with motorists at one period of the year.

Lord BERTIE intervened to ask whether Earl Russell would also consider the protection of doctors who were left without payment.

Earl RUSSELL said he thought doctors were protected, as they could sue. An injured person could recover damages, which included medical fees, but in some cases where a patient had been treated at a hospital, although he recovered damages that included medical fees, they were not necessarily paid over to the hospital. He added an assurance that he would consider everything that any person interested in the matter represented to him.

Lord Luke's amendment, and Viscount Bertie's amendment to it, were then both withdrawn.

Tuberculous Milk.—On December 23rd Miss LAWRENCE informed Mr. Somerville Hastings that the average proportion of milk samples taken by the larger local authorities and found to be tuberculous had recently been 6 per cent. The results obtained by different authorities fluctuated considerably, and it would be difficult to say that the percentage for the whole country was either increasing or decreasing. In reply to a further question, Miss Lawrence told Mr. Hastings that the number of milch cows in this country which had been submitted to a tuberculin test was relatively few. It was not possible, therefore, to say what proportion would react to the test, or whether that proportion was increasing or decreasing.

Tests for Detecting Tuberculosis in Dairy Cattle.—Colonel GAULT asked, on December 19th, whether the Empire Marketing Board would consider making a grant for testing the varying efficiency of the present tests employed for detecting tuberculosis in dairy cattle, and whether there was any colonial evidence to show that the milk from certain types of cow condemned as tuberculous was capable of transmitting the disease to human beings. Mr. LUNN replied that in such matters the Empire Marketing Board was guided by advice received from the Ministries of Health and Agriculture in Great Britain. It would be for those departments to take the initiative in instituting such inquiries.

Shortage of Accommodation in Public Mental Hospitals.—Answering Mr. Sorensen, on December 19th, Mr. GREENWOOD said that, though there was a shortage of accommodation in public mental hospitals, there were relatively few cases of serious overcrowding. The position had already received his attention. Approval had been given to certain proposals for extending mental hospital accommodation, and others were under consideration. It was anticipated that these extensions would largely meet the shortage. Further alleviation of the position might result from the survey of institutional accommodation which might become available under the Local Government Act. He was aware that institutional accommodation for mental defectives, both adults and juveniles, was inadequate. Local authorities were being urged to carry out their statutory duty to provide institutional accommodation. Answering further questions, Mr. Greenwood said some local authorities had been deterred by the expense of providing this accommodation, but a committee had been appointed to recommend ways of reducing the cost. Local authorities had been urged to undertake their duty in this regard, and he hoped that the shortage of accommodation would soon be remedied

War Pensions.—On December 23rd Mr. F. O. ROBERTS told Mr. Beaumont that the primary points of difference between his policy and that of his predecessor in procedure in dealing with seven-year limit applications were that no claim would be rejected solely on the ground of the time limit; that every applicant would be invited to state his case and to give evidence in support of it in response to specific inquiries tending to elucidate the claim; that full consideration (including medical examination wherever necessary) would be given to all evidence submitted, and War Pensions Committees had been instructed to consider and investigate complaints from applicants whose claims had been rejected and to report specifically on them to the Ministry; and, finally, that in the determination of all cases of material doubt or difficulty independent medical experts, nominated by the Presidents of the Royal College of Physicians and the Royal College of Surgeons, would be regularly associated with the Ministry.

Blind Pensioners.—Mr. ADAMSON stated, on December 24th, that the Scottish Department of Health is of opinion that, save in cases of total blindness, blind pensions should, as a rule, only be awarded in future on the advice of an eye expert. Previously, he added, the Department had held that such pensions could safely be awarded on the advice of medical officers who were not specialists. Dr. VERNON DAVIES followed up this statement by asking whether Mr. Adamson held that a specialist was required to decide whether a man could see or not. Mr. ADAMSON replied that he thought that in certain cases a specialist was required to judge.

Health of the Mercantile Marine.—On December 24th Mr. GRAHAM supplied Dr. Fremantle with a statement on the work of the committee set up a year ago to advise on any questions affecting the health of the mercantile marine which the Board of Trade or Ministry of Health might refer to it. He said the committee's advice on questions was submitted to the departments as consideration of each subject was completed. No general report was published. The committee had already dealt with the *Ship Captain's Medical Guide*, which had been revised and issued. The scales of medicine and medicinal instruments and stores for ships which did not carry surgeons had also been revised and issued. A code for facilitating medical consultation at sea by wireless telegraphy had been completed and forwarded to the International Code of Signals Committee. The hygiene of crew spaces on board ship and the statistics relating to the mortality of seamen were under investigation

Committees connected with Public Health Administration.—Mr. GREENWOOD, on December 19th, furnished Mr. Llewellyn Jones with the following list of committees set up by the Ministry of Health in connexion with the administration of National Health Insurance or of public health generally since 1925:

Committee on Post-Graduate Medical Education.
Committee on Vaccination.
Dental Benefit Joint Committee—which has now been replaced by the Dental Benefit Council.
Advisory Committee under Therapeutic Substances Act, 1925.
Medical Advisory Committee on Decennial Revision of International List of Causes of Death.
Committee on the Optical Practitioners (Registration) Bill.

Joint [illegible] tion of Rivers and Streams.
Advis[illegible] tion of Drugs for the purposes of Medical Benefit under the National Health Insurance Acts.

Dr. FREMANTLE asked whether the general effect was that this side of the scheme on which the Ministry of Health was established had not been a dead letter since its formation. No answer was returned.

Criminal Lunatics in Scotland.—On December 24th Mr. ADAMSON informed the Duchess of Atholl that in 1926 the number of persons convicted in Scotland as criminal lunatics was 17, of whom 4 were of Irish nationality. In 1927 the number was 24, of whom 3 were Irish, and in 1928 the number was 18, of whom 3 were of Irish nationality.

Slum Clearance.—In reply to Mr. Louis Smith, on December 19th, Mr. GREENWOOD said he hoped to introduce the Government's Slum Clearance Bill on an early day after the Christmas recess. Answering Mr. Smithers, Mr. Greenwood said that since the Government took office six slum clearance schemes had been submitted, the estimated cost of which was £511,000.

Extension of Town-planning Powers to Built-up Areas.—Dr. FREMANTLE asked, on December 19th, whether Mr. Greenwood's attention had been called to the development of certain properties in the West End of London, such as the sites of Grosvenor House and Devonshire House, Westminster, and Hereford Gardens, near Marble Arch, whereby large new populations were housed without regard to the traffic capacity of the serving streets; and when he proposed to introduce legislation to enable developed areas to be re-planned and the population to the acre limited. Mr. GREENWOOD said he was aware of the type of development to which Dr. Fremantle referred. He hoped in due course to introduce legislation for extending town-planning powers to built-up areas. Replying to a further question from Dr. Fremantle, Mr. Greenwood suggested that this would be difficult to combine with the promised Housing and Slum Clearance Bill, as town-planning had been dealt with in separate statutes.

Telephone Services in the Hebrides.—On December 23rd Mr. LEES-SMITH, replying to Mr. Ramsay, who asked if he would consider the advisability of establishing a telephone in the doctor's house, schoolhouse, or other centre, in every parish in the Hebrides, for medical and surgical services, said that the distances between parishes in these islands were often great, and the cost of providing telephone services was usually prohibitive. Any case in which there was a reasonable prospect of the revenue not falling too far short of the expenses was, however, sympathetically considered.

Paint-spraying.—Mr. SORENSEN asked, on December 19th, whether Mr. Clynes was aware of the harmful effects of paint-spraying, both on the operators of the machines and on others in the vicinity, and whether he would introduce legislation to safeguard the health of such workers. Mr. SHORT replied that paint-spraying was not necessarily harmful. So far as the Home Office knew, any cases of risk to health could be effectively dealt with under the Factory Acts and Lead Paint Acts. Mr. Clynes would, however, be glad to make further inquiry if furnished with particulars.

Notes in Brief.

Mr. Greenwood states that as the Radium Trust is appointed by Royal Charter he is not able to anticipate any decision which may be taken by the Trust on the future purchase of radium from Radium Belge or from other firms.

Miss Lawrence, replying to Major Hills, on December 23rd, said that the question of compiling from the 1931 census statistics of the mortality of married women by reference to the occupation of the husband would be considered, though such supplementary tabulations could not be undertaken until the completion of the census tabulation. Statistics on the association of maternal mortality with the parents' occupations would also be considered.

Mr. Clynes told Mr. Freeman, on December 18th, that the average number of experiments on living animals in connexion with cancer during the last ten years was 13,369. These figures represented the number of experiments performed at special cancer research centres and those done elsewhere under grants from the Medical Research Council and the British Empire Cancer Campaign, in addition to some experiments probably done by licence holders for private research, though the latter number was small.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following candidates have been approved at the examination indicated:

FINAL B.M., B.CH.—(*Medicine, Surgery, and Midwifery*): J. A. Brown, J. L. Clapham, C. M. Duncan, W. B. Fiddian-Green, J. K. Marshall, Q. St. L. Myles, R. S. B Pearson, C. R. Salkeld, W. A. Secker, W. B. Williams, Annie D. M Adams, Ruth Sandeman, (*Materia Medica*): R. A. Beaver, W. D. W. Brooks, W. D. T. Brunyate, P. G. Burgess, A. J. Carpenter, N. A. Gillespie, W. E. S. Merrett, J. A. Nunn, M. W. C. Oldfield, A. G. Palin, J. A. E. Scott, R. B. Scott, Elizabeth C. M. Brunyate, Amy C. E. Clarke. (*Pathology*): R. E. Adam, I. M. Bell, W. D. W. Brooks, G. H. Buck, J. M. Cribb, F. R. Crookes, S. Durham, N. A. Gillespie, N. Heath, G. W. Hinchliff, J. E. Jenkins, H. de B. Kempthorne, G. B. Malone-Lee, J. H. Peel, W. S. Tegner, H. A. Treble, F. M. Trefusis, O S. M. Williams, Elspeth W. Smellie. (*Forensic Medicine and Public Hygiene*): H. H Aitchison, F. Bell, W. D. T. Brunyate, G. H. Buck, J. L. Clapham, C. M. Duncan, W. B. Fiddian-Green, C. R. Greene, A. Guirdham, F. Hawking, W. H. McMenemey, J. K. Marshall, W. E. S. Merrett, R. D. Newton, J. N. O'Reilly, N. C. Parfit, R. S. B. Pearson, F. M. Trefusis, Amy C. E. Clarke, Victoria M. Robinson.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examinations indicated:

M.CHIR.—F. J. Milward.

THIRD M.B. (*Part I, Su[illegible] and Gynæcology*).—G. G. Allan, G. N. Bailey, G. O. [illegible] in surgery only), J. H. Bentley, R. M [illegible] D. D. Broughton, A. C. Crooke, A. M. Cunningham, H. Curtis, M. Ellis, R. B. Floyd, M. S. M. Fordham, I. J. Franklen-Evans, A. W. Franklin, A S. Hall, P. E. T. Hancock, A. G. J. Harris, J. E. M. Harrisson, F. T. J. Hobday, W. V. Howells, E. H. Hudson, C. G Jobbins, M. M. St. G. Johnstone, J. G. Jones, H. V. Knight, E. Landau, R. S. C. McDade, S. McDonald, A. P. McEldowney, R. W. Malim, C. E. P. Markby, R. A. Maynard, B. C. Nicholson. G. L. Ormerod, R. G. Orr, V. P. Paxon, J. O. Poynton, C. B. Prowse, T. G. Reah, G. H. Sanderson, J. E. Semple, R. H. B. Snow, G. H. G. Southwell-Sander, R. S. Stacey, E. T. W. Starkie, B. C. Thompson, C. P. K. Toland, F. S. Winton; Women—C. H. England, D. P. Firmin. (*Part II. Principles and Practice of Physic, Pathology, and Pharmacology*): R. Anderson, A. R. Banham, C. M. Barker, D. W. Bawtree, J. V. Broad, A. T. Curnow, C. J. M. [illegible] R. H. Dyer, J. H. L. Easton, P. H. F [illegible] A. H. Gurney, W. Heath, A. C. [illegible] G. Herbert, H. P. Hutchinson, T. C. Jameson Evans, C. G. Jobbins, E. R. Keeble, R. W. Knowlton, O. L. Lander, R. W. McConnel, S. R. Matthews, R. B. Mayfield, E J. Neill, T. N. Parish, J. A. Pocock, C. D. Politeyan, R. B. Pringle, A. W. Williams, J. K. Willson-Popper, G. N. Wood, F. G. Wood-Smith, B. Wright; Women—M. A. Willcox.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

M.D.—*Branch I* (*Medicine*): B. Barling, F. M. M. Eyton-Jones, C. F. Fernando, T. R. Hill, B. B. Hosford, R. M. Maher, H. L. Marriott, R. L. Midgley, N. D. Patel, W. M. Ramsden, B. F. Russell, E. W. Skipper, E. C. Warner. *Branch II* (*Pathology*): G. W. J. Bousfield, Beatrice D. Pullinger, Dorothy M. Vaux. *Branch IV* (*Midwifery and Diseases of Women*): Janet I. Hoare, Winifred A. Ladds, Edna I. Langston, Isabella L. H. Livingstone. *Branch V.* (*State Medicine*): G. E. Brocklehurst, S. C. Gawne.

M.S.—*Branch I* (*Surgery*): A. W. Holgate, N. P. L. Lumb, R. W. Reid. *Branch III* (*Ophthalmology*): J. W. T. Thomas.

UNIVERSITY OF SHEFFIELD.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—*Part I;* K. G. A. Barlow, C. England, M.B. Hallam, F. Hudson (with distinction in Forensic Medicine and in Public Health), Constance N. Jenkinson, S. K. Panniker, A. Spencer. *Part II:* A. Cohen, R. B. Gould, Bessy Hatherley, J. H. Wilbourn.

UNIVERSITY OF EDINBURGH.

A THREE months' course of instruction for the diploma in psychiatry will commence on January 14th. During its currency candidates are eligible for resident clinical clerkships at the Royal Edinburgh Hospital for Mental Disorders. Full particulars can be obtained on application to the Dean of the Faculty of Medicine, University of Edinburgh.

A graduation ceremony was held in the Upper Library Hall on December 20th, 1929, when the following degrees were conferred:

M.D.—Flora H. M. Calder, *T. C. Mitchell, *R. M. Murray-Lyon, E. Russell (*in absentia*), G. S. Scott, †Ta-Ming Tso.

CH.M.—*Alice Bloomfield.

M.B., CH.B.—W. S. Anderson, R. Austin, I. Bannerman, T. M. Beveridge, G. F. Bradbury, R. M. Bremner, J. F. C. du Toit, F. G. M. Fraser, E. E. Goldman, J. Gorman, D. H. Hooper, E. G. Hurd-Wood, I. Kaplan, H. I. Lahouri, L. E. Lucas, K. C. Mackenzie, A. C. M'Laren, D. J. A. MacLean, D. Macleod, H. J. Melville, G. R. Parker, J. L. Parker, R. A. P. Paul, G. A. G. Peterkin, J. C. Robertson, N. Talukder, Anne Tillema, S. C. H. Watters.

D.PSYCH.—T. A. H. Munro.

D.P.H.—K. V. R. Choudari.

* Highly commended for thesis.
† Commended for thesis.

The Syme Surgical Fellowship has been awarded to Dr. T. C. Mitchell.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE following candidates have been approved at the examinations indicated:

PRIMARY FELLOWSHIP.—E. A. J. Byrne, S. F. Heatley, D. S. Poole-Wilson.

FINAL FELLOWSHIP.—B. P. Baliga, C. R. Boland, E. N. McDermott, K. F. Mackenzie, P. P. V. C. Nambiar.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examinations indicated:

FINAL PROFESSIONAL.—M. J. Duffy, A. E. Flannery, T. J. Harkin, G. J. Harrison, J. Lennon, P. B. McCarthy, T. McCarthy, T. J. A. McHugh, P. McInerney, W. H. Peirce, F. O'C. Walsh, J. R. H. Weir.

D.P.H.—W. R. F. Collis, J. J. McHenry.

D.P.M.—J. F. Lyons, C. B. Bamford.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—J. S. Bury, D. Ram Annamalai, B. T. Squires, C. D. Trimble.

MEDICINE.—C. W. Ellison, V. J. Lopez, L. J. Pearson, T. G. Robinson, B. T. Squires.

FORENSIC MEDICINE.—C. E. P. Davies, W. J. D'Rosario, R. J. Kagan, V. J. Lopez, D. Ram Annamalai, B. T. Squires.

MIDWIFERY.—T. Chandrasekharan, G. P. Charles, W. J. Frith, R. J. Kagan, I. W. H. Mansfield, P. Somasunder, L. J. P. Soromenho, B. T. Squires, C. D. Trimble.

The diploma of the Society has been granted to Messrs. W. J. Frith, R. J. Kagan, V. J. Lopez, and B. T. Squires.

Medico-Legal.

OFFENCES UNDER THE DANGEROUS DRUGS ACTS.

AT Maidenhead police-court, on December 2nd, 1929, Richard William Starkie, formerly a metropolitan police surgeon, was sentenced to twelve months' imprisonment in the second division on summonses under the Dangerous Drugs Acts. He appealed to the Berkshire quarter sessions on December 20th, when the sentence was reduced to one of five months in the second division. In 1921 Mr. Starkie was sentenced to nine months' imprisonment for administering noxious drugs to a woman, and in consequence of that conviction his name was erased from the *Medical Register* in 1922 (*Supplement*, i, 1922, p. 217).

Outlining the present charge at the appeal proceedings, Mr. W. G. Earengey, for the Crown, said that in July last a man named Melville or Vilmer presented to a chemist a prescription for 8 grains of heroin. Over a period of three months twenty-three such prescriptions were handed in, all for a patient named Mrs. Melville, and Starkie agreed that his signature was on sixteen of them. To a police inspector he said that he had given Melville sheets of blank paper bearing his signature, which Melville had filled in in certain eventualities.

Chief Inspector Prothero said that until his conviction in 1921 Starkie's character was good, and he had an extensive medical practice. Since his release from prison in 1922 the police had known nothing to his detriment. There was no suggestion of drug traffic in this case.

Mr. A. R. Thomas, for Mr. Starkie, complained that in the police-court proceedings the advocate told the magistrates that he had instructions from the Home Office to say that the department regarded the case as a serious one. "Government departments have a good deal of authority thrust upon them by Acts of Parliament, and in many cases duties which formerly devolved upon justices come into their charge. But what justification can there be for someone sitting at the Home Office and, not having heard a single word in court, forming a certain conclusion about the case?"

The chairman of the sessions (Mr. C. M. Pitkin, K.C.) agreed that it should not have been mentioned, and certainly should not have had the slightest effect upon the magistrates.

Mr. Thomas further urged, on behalf of the appellant, that there was no suggestion here of traffic in drugs or of supplying prescriptions wholesale for money. All that Starkie had received was two worthless cheques, and he had no hope of getting anything. Two registered medical practitioners had been persuaded by Melville, as Starkie had been, to allow him to fill up the body of the prescriptions, and had been convicted for not keeping proper drug records. Melville was the villain of the piece, and it was he who should suffer. Starkie had been trying to get back on the *Medical Register*, and but for "this stupid business" might by now have succeeded.

The chairman said that the bench regarded the offences as flagrant and serious breaches of the regulations, which could not be punished in any other way than by imprisonment. They thought, however, that the sentence of twelve months' imprisonment was excessive, and reduced it as stated.

Medical News.

THE Hunterian Society of London will hold a banquet at the May Fair Hotel on Thursday, February 13th, at 7.30 o'clock, to commemorate the 202nd anniversary of the birth of John Hunter.

THE Harrison Memorial Lecture before the Pharmaceutical Society of Great Britain will be delivered on Tuesday, January 14th, at 8.30 p.m., at 17, Bloomsbury Square, W.C., by Mr. P. A. W. Self, B.Sc., Ph.C., who will be presented by the president of the society with the Harrison medal. This lectureship and medal were established to perpetuate the memory of Colonel E. F. Harrison, C.M.G., director of chemical warfare during the war, and a distinguished member of the Pharmaceutical Society. The prize founded by the Chemical Society in 1922, in memory of Colonel Harrison, has been awarded to Dr. R. P. Linstead. This prize is awarded every three years to the chemist, under thirty years of age, who during the preceding five years has produced research work judged to be of the greatest merit and promise. The prize will be presented at the annual meeting of the Chemical Society in March. It may be recalled that Harrison had been associated with the *British Medical Journal* for some years, and undertook the series of analyses of proprietary articles, afterwards collected and published by the British Medical Association in the two volumes *Secret Remedies* and *More Secret Remedies*, now out of print. He also gave evidence on behalf of the Association before the Select Committee on Patent Medicines, and the care he had spent in preparing his case and the transparent honesty with which he presented it made a deep impression on the committee.

THE annual meeting of the St. George's Hospital Ladies' Association will be held in the board room of the hospital, Hyde Park Corner, S.W., on Thursday, January 9th, at 3 p.m., under the presidency of Princess Marie Louise. Sir Humphry Rolleston will speak on the training of nurses.

A CLINICAL meeting will be held at the East London Hospital for Children, Shadwell, E.1, on Wednesday, January 8th, at 4.15 p.m., when cases of interest will be demonstrated in the wards. Tea at 4 o'clock. All practitioners are welcome.

A POST-GRADUATE course on diseases of the nervous system will be given at the National Hospital from February 3rd to March 28th. The general course will consist of thirty-two clinical lectures and demonstrations, teaching in the out-patient department, and eight pathological lectures and demonstrations. The fee for the course is £6 6s. A course of eight lectures on the anatomy and physiology of the nervous system will be arranged on Fridays at 12 noon if there are sufficient applicants; fee £2 2s. A series of twelve demonstrations on methods of examination of the nervous system will be given on Tuesdays and Thursdays at 12 noon; fee £2 2s. Further particulars can be had from the secretary, Medical School, National Hospital, Queen Square, W.C.1.

THE Medical Faculty of Vienna has arranged for an international post-graduate course to be held from February 17th to March 1st, in medical, surgical, and gynaecological therapeutics, with special reference to recent developments. Further information may be obtained from Dr. A. Kronfeld, Porzellangasse 22, Vienna IX.

THE KING has granted Dr. P. S. Selwyn-Clarke, *M.C.*, permission to wear the decoration of the Médaille d'Argent des Epidémies conferred upon him by the French Government for services in connexion with the outbreak of yellow fever in West Africa.

A SELECT Committee, appointed by the House of Commons to examine and classify petitions presented to the House, has reported on its work between July 2nd and December 18th, 1929, in a circular issued by the Stationery Office. Among the petitions was one praying for the prohibition of vivisection, and the committee states that it has not reported the total number of names appended, since it is of opinion that some of the signatures are in the same handwriting, and that therefore there has not been compliance with the orders of the House requiring the actual signatures of the persons named. The figure recorded by the committee, after ignoring these irregular signatures, is 3,549.

A LARGE gathering of past and present students of University College, London, attended a dinner which was held on December 19th, 1929, at the Connaught Rooms, with Sir Frank Heath, president of the Old Students' Association, in the chair, in honour of the Provost, Sir T. Gregory Foster, on the occasion of his retirement. During the evening, Sir George Blacker, Professor R. W. Chambers, Dr. Harriette Chick, and Mr. R. C. Wright presented the guest with an illuminated portfolio—the work of Miss Margaret Alexander, a former student—containing the signatures of the company present at the dinner. Sir Gregory Foster, in replying to the toast of "The Provost" which had been proposed by the chairman, said that there was nothing they could congratulate the country upon more than its faith in the scholastic profession, and its desire to put that profession in its right place in the country and the Empire.

THE German Society for Internal Medicine will hold its forty-second congress, under the presidency of Professor Volhard of Frankfort, at Wiesbaden from April 7th to 10th, when the following subjects will be discussed: the hypophysis, introduced by Trendelenburg of Berlin, and focal infection, by Rosenow of Rochester. Further information can be obtained from Professor Volhard, Süd 10, Medizinische Klinik, Frankfort.

UNDER the auspices of the Physical Society and the Optical Society the twentieth annual exhibition of electrical, optical, and other physical apparatus will be held at the Imperial College of Science and Technology, South Kensington, on January 7th, 8th, and 9th, in the afternoons from 3 to 6, and the evenings from 7 to 10. Tickets for others than members of the Physical or the Optical Society, together with a copy of the catalogue, may be obtained by sending 3d. in stamps for postage to the secretary of the exhibition, 1, Lowther Gardens, Exhibition Road, S.W.7.

THE ninth Italian congress for medical radiology will be held at Turin, under the presidency of Professor M. Bertolotti, in May, when the subjects for discussion will be the radiological diagnosis of intracranial tumours and the treatment of blood diseases by irradiation.

THE fifth international congress of physiotherapy will be held at Liège from September 4th to 8th, 1930.

AN international congress of neurology will be held at Bern in August and September, when the chief subjects for discussion will be muscular tonus, diagnosis and treatment of cerebral tumours, and injuries and infections of the nervous system.

DR. HASSELBACH of Copenhagen, whose son died of leukaemia at the age of 15, has given a sum of 700,000 kronen, the interest on which is to help Danish practitioners in researches on leukaemia.

THE issue of *Schweizerische medizinische Wochenschrift* for December 7th is devoted to the proceedings of the sixteenth congress of the Swiss Surgical Society held at Zug on July 25th and 26th.

DR. CHARLES NICOLLE, director of the Pasteur Institute at Tunis, has been elected member of the Académie des Sciences.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF PRURITUS VULVAE.

"R. S." writes: I have a patient, aged 27, who suffers from intolerable pruritus vulvae, which has now lasted for several years. The irritation commences on the inner side of the left labium majus, and the patient can put her finger exactly on the spot. The irritation then extends into the vagina, until the patient, almost hysterical, douches the vagina with plain hot water, which gives relief for some hours. Vaginal, urinary, and rectal examinations are all negative. The patient has been under a prominent gynaecologist, who dilated and curetted, and also tried various treatments for months, but quite unsuccessfully. I have used every conceivable form of remedy I can imagine; bromides, calcium, thyroid, suppositories, douches, ointments, lotions, etc. If any readers can give me any suggestion for treatment which they have found useful I shall be much obliged.

INSULIN FOR SENILE DIABETICS.

"DISTRICT MEDICAL OFFICER" would like to hear of some simple plan for giving insulin in very small doses to parish patients about 80 years old. They suffer from senile diabetes of a type which cannot quite be controlled by diet alone, and they are unable or unwilling to go to institutions to have their blood sugar determined.

WINTER MOTORING.

"H. G." (*Blackpool*) writes: With reference to your article "Winter Motoring" in the *Journal* of December 7th (p. 1061), concerning antifreezing media of glycerin and water, I should be glad to know if this method has any harmful effects in any respect on the engine. Also, when desiring to finish with this mixture, should one simply drain the radiator or refill with water?

*** Our Motoring Correspondent writes: If the recommended proportions of glycerin and water are adhered to, the mixture will have no harmful effects on the engine or the water-circulating system. From this it follows that no special attention will be necessary as soon as the need for the mixture is over, when it can be drained and replaced by water.

INCOME TAX.

Change in Nature of Appointment.

"D. N. P." qualified in April, 1928, and during the year ending April 5th, 1929, his total income was £100. Since February 19th, 1929, he has held a resident post at a hospital at a salary of £300 per annum. What is his liability to tax for 1928-29 and 1929-30?

*** 1928-29: No liability, but "D. N. P." must, of course, make a statement of his total income in due form, if called upon to do so. 1929-30: £300 *less* £135=£165 at 2s. in the £—that is, £16 10s.; this assumes that he cannot claim relief in respect of life assurance, dependent relative, or marriage, and that he has no other income than the salary of £300.

LETTERS, NOTES, ETC.

GLUCOSE IN ASTHMA.

DR. H. N. MUKHERJEE (Biochemical Department, Carmichael Medical College, Calcutta) writes: With reference to Dr. Arthur F. Hurst's letter on "Glucose in the treatment of asthma" (*Journal*, November 16th, 1929, p. 930), may I draw attention to the fact that *Dr. B. C. Roy and myself* reported a condition of hypoglycaemia and acidosis (decrease in the alkali reserve) in asthma as early as 1923 (*Calcutta Medical Journal*, March, 1923, p. 12). For some years we have been using glucose together with sodium bicarbonate in the treatment of asthma, often with very good results. I may also add that Dr. W. Langdon Brown, in his opening paper on the treatment of asthma at the British Medical Association Annual Meeting held at Bath in 1925, referred to our work (*British Medical Journal*, August 29th, 1925, p. 368).

MR. FISHER'S STUDY OF CHRISTIAN SCIENCE.

LIEUT.-COLONEL S. P. JAMES, I.M.S.(ret.), writes: On the recommendation contained in the review of *Our New Religion*, by the Right Hon. H. A. L. Fisher, which appeared in the *Journal* of December 7th, 1929 (p. 1059), I bought the book and sent it to a friend as a Christmas gift. My friend tells me that he does not agree with the reviewer's opinion that the book is "a very brilliant piece of work," for the following reasons: (1) Mr. Fisher *has omitted to quote literature which conflicts with the kind of* history which he desires to record. For example, he has omitted from his list of "primary authorities" Mrs. Eddy's well-known book *Miscellany*, in which, on page 308, there is a detailed correction of the information contained in the article in *McClure's Magazine*, from which Mr. Fisher has evidently drawn most of his historical account. (2) Mr. Fisher is guilty of misquotation, as, for example, on page 214 of his book, where he quotes from Mrs. Eddy's chapter on prayer in *Science and Health*. In the last line of this extract from that book he quotes her as saying, "let our words attest our sincerity," whereas what is actually printed on page 15 of *Science and Health* is "let our lives attest our sincerity." My friend points out that there is an important difference between these two pieces of advice which Mr. Fisher has apparently failed to notice. I have been at some pains to consult the references mentioned, and have ascertained that my friend's statements are correct.

ARTERIO-SCLEROSIS IN COAL MINES.

DR. N. PINES (London, E.), in the course of a letter discussing the paper by Drs. D. Elliot Dickson and W. Arnott Dickson on arterio-sclerosis in coal miners (December 14th, 1929, p. 1103), writes:—Criticism may be directed to the following points: (1) the complete absence of ophthalmoscopical examination; (2) the suggestion that arterial thickening felt by palpation is due to calcareous degeneration. *In vivo* calcium is deposited in a semiliquid or colloid form, and therefore cannot be felt by palpation. One can feel the thickened or contracted arterial wall, but not the deposited calcium. May I suggest that the cause of vascular degeneration in miners is probably fine coal-dust, which is inhaled in large quantities by underground workers.

DISCLAIMER.

DR. A. T. TODD (Bristol) writes: I should like it to be known that I had no knowledge of or participation (active or passive) in the notices of our work on the treatment of cancer which have just appeared in the lay press.

1930 MOTOR LICENCES.

To assist motorists in connexion with the renewal of car and motor-cycle licences for the new year, the Automobile Association has issued a booklet, entitled *Your Motor Tax at a Glance*, which shows the various amounts due for licences, according to horse-power, either for the year or shorter periods. Information is also given concerning rebates obtainable in respect of old cars, refunds for surrendered licences, and the necessary procedure for renewing licences. It is important to bear in mind that the authorities grant fourteen days' grace for the renewal of licences, and that vehicles used during this period of grace become liable to taxation. Copies of the booklet may be obtained on application, by postcard, to the secretary of the A.A., Fanum House, New Coventry Street, W.1, or to any of the area offices.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 46, 47, 48, 49, 52, 53, 54, 55, and 56 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 7.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

1. Inversion of the T-wave in Ventricular Strain.

A. R. BARNES and M. B. WHITTEN (*Amer. Heart Journ.*, October, 1929, p. 14) have attempted to analyse the influence of right and left ventricular strain in producing significant inversions of the T-wave. The authors' series comprised 177 patients who showed such electro-cardiographic changes, but inversion of the T-wave in Lead III alone was not regarded as having any significance. Not only were these patients investigated clinically, but in each instance a detailed pathological study was made at necropsy. The cases in which strain had *fallen principally on the left ventricle* were separated; this group consisted of patients suffering from present or pre-existing hypertension with or without coronary sclerosis, syphilitic aortic incompetence, and aortic endocarditis with stenosis or incompetence. Of these patients 84 per cent. showed inversion of the T-wave in Lead I, or Leads I and II; in all but two cases where this change occurred in Leads II and III infarction was found in the posterior surface of the left ventricle. Six patients in whom strain had fallen predominantly upon the right ventricle were investigated; this group included cases of mitral stenosis, mitral incompetence, and chronic pulmonary disease, and five of them showed inversion in Leads II and III. In the sixth case the T-wave was diphasic in all leads. There were twelve patients with such combinations of diseases that strain could have been exerted upon both ventricles; the T-wave was inverted in Leads II and III in seven of them. The right ventricular strain arose in all these cases from a mitral insufficiency, and this complication was apt to produce inversions in Leads II and III even when there was marked left-sided strain from hypertension. The authors found that large hearts gave a high percentage of T-wave inversions in Lead I, or in Leads I and II, this being in accord with the clinical observation that a clear-cut strain on the left ventricle is produced by those conditions which give rise to most cardiac enlargement. Among the patients studied were 52 suffering from myocardial infarction; it was observed that where infarction resulted from left coronary obstruction the T-wave was inverted in Lead I, or in Leads I and II. On the other hand, if those parts of the heart supplied by the right coronary artery became infarcted, the inversion occurred in Leads II and III.

2. Erythraemia at High Altitudes.

C. MONGE (*Arch. des Mal. du Cœur*, October, 1929, p. 651) has studied the morbid states produced by residence at altitudes of about 11,000 feet. He classifies patients into three groups: the first comprises those who are taken ill during rapid transit from sea level to high altitudes; the second consists of patients living at high levels who may have passed through an acute stage of maladaptation; the third class of case occurs among acclimatized residents who may have passed their whole lives on the mountain and who in later years suffer loss of acclimatization. Outlining the salient features of mountain sickness, the author mentions general vasodilatation, erythraemia up to seven millions, cyanosis, and breathlessness; vomiting and diminution of physical and mental capacity follow, and unless the patient returns to a lower level he is liable to increasing symptoms with cardiac insufficiency and suppression of urine. But in addition to this classical type, the author describes a more chronic condition which may supervene in those thought to be acclimatized, but who suffer from headache, breathlessness on exertion, and muscular pains, while considerable erythraemia ar[illegible] are discovered on examination. T[illegible] occurring among those who fail to[illegible] among those residents who lose their tolerance, are the severest. Removal to lower altitudes is almost invariably followed by improvement and rapid cure, some degree of tolerance being acquired, but if the patient returns to high levels the malady always recurs sooner or later. Examination of the blood of residents at high altitudes shows a characteristic reduction in the arterial oxygen saturation which is compensated by increase in the haemoglobin. In the more severe types of erythraemia oxygen is actually circulating in excess in the blood, but there is a failure of utilization on the part of the tissues. The relationship between altitudinal erythraemia and Vaquez's disease is not understood. The principal distinctions are that the former disease is cured either by acclimatization or by descent to lower levels, while it is suggested that loss of permeability in the lung is a feature in the pathogenesis of both conditions.

3. The Thyroid Gland and Rheumatism.

LAUTIER (*Bull. Soc. de Ther.*, October 9th, 1929, p. 165), who records three cases in female patients aged 15, 23, and 38 respectively, illustrates the frequency of a rheumatic origin of toxic thyroid adenoma and exophthalmic goitre by the fact that it was found in 25 per cent. of 250 cases of exophthalmic goitre collected by Mouriquand and Bouchut, and in 23 out of Froment's 33 cases, though he regards this as too low an estimate of the real frequency. In the early stage of thyroid intoxication extra-systoles, or a tachycardia of 100 to 150, and occasionally slight cardiac hypertrophy, are found. Subsequently disturbances of rhythm become prominent and the patient presents attacks of paroxysmal tachycardia, auricular flutter, and auricular fibrillation which is at first transient and finally permanent; occasionally pulsus alternans and heart-block appear. The last stage consists of cardiac insufficiency characterized by the typical symptoms of cardiac failure. The cardiac manifestations of exophthalmic goitre may be due to primary infection of the thyroid, giving rise to hyperthyroidism and dysthyroidism or to a simultaneous local infection of both the heart and thyroid. There is no doubt that both processes may be encountered. In the first cases severe symptoms of cardiac failure may disappear after thyroidectomy, but such an event is rare. In the more frequent cases in which the thyroid and heart are affected simultaneously the causal infection is often rheumatism. In such cases the administration of anti-rheumatic vaccine cures the cardiac insufficiency and restores the functional power of the myocardium.

4. Tobacco Smoking and Gastric Symptoms.

I. GRAY (*Ann. Int. Med.*, September, 1929, p. 266) made a study of the relation of gastric symptoms to tobacco smoking in 400 individuals, who were divided into two groups. One group consisted of 300 patients who had functional gastric disturbance and gave a history of tobacco smoking, and the other of 100 patients with organic gastric disease who also gave a history of tobacco smoking. The ages in both groups ranged from 25 to 65 years, and there was a history of tobacco smoking for at least five years. Of the entire group, 5 per cent. were women in whom the gastric disturbance was of a functional nature. Most of the patients were cigarette smokers. About one-fifth smoked cigars only, some smoked cigars and cigarettes, and very few smoked pipes. Gray concludes that tobacco smoking is an etiological factor in gastric disturbances, but individual sensitivity rather than the amount of tobacco consumed is the determining factor in the symptomatology. The secretory and motor responses in individuals with gastric disturbances due to tobacco smoking vary in spite of similarity in clinical symptoms. About one-fourth of those patients with functional gastric disturbances attributable to tobacco smoking show hyperacidity, and about one-fifth subacidity. In peptic ulcer tobacco smoking usually causes an increase of gastric secretion during the fasting stage, and hyperacidity in about one-third. Clinical improvement in some of these patients with ulcer occurred only after cessation of smoking. The therapeutic test, and not the clinical and x-ray findings, determines the conclusion whether the person should smoke or not.

5. Azotaemia in Urinary Diseases.

H. BLANC (*Gaz. Hebd. des Sci. Méd. de Bordeaux*, November 3rd, 1929, p. 633) criticizes the tendency to accept a single blood urea estimation as indicative of the presence or absence of a high urea content. When the estimation is made it is important to note whether the patient is on a normal, high, or low protein diet, and the test should be performed again under different conditions. Thus, a blood urea figure of 50 mg. per cent. may not be excessive for a gross eater on a high protein diet, whereas one of 40 mg. per cent. may be so for another patient on a low diet. Moreover, oliguria or chloride retention may vitiate the estimation. Medical diseases of the kidney mostly give rise to the syndrome described by Guyon as "renal dyspepsia," indicated by a dirty tongue, a distended abdomen, loss of appetite, diarrhoea or constipation, and haemorrhagic phenomena, but the existence of cases of "ambulatory azotaemia" not showing these signs must not be forgotten. Blanc remarks that it might be supposed that essential renal disease would more or less rapidly give rise to azotaemia, but this is not always so; medical cases of cardio-renal or of Bright's disease sooner or later cause azotaemia, whether they take the hypotensive or the chloride retention form, but surgical diseases show another picture. The phenomenon

of "compensatory hypertrophy" plays an important part in disease necessitating nephrectomy, or even where there is extensive bilateral disease such as tuberculosis; and in such conditions it is not azotaemia, but toxaemia, which commonly kills; pyelonephritis is an exception. Azotaemia tends to occur in surgical diseases leading to retention of urine by obstruction of the upper or lower part of the urinary tract; the discovery of a high blood urea has even in some cases led to the discovery of retention due to calculus. The prognosis of azotaemia due to retention is relatively good where the retention can be relieved, and cases have occurred where a blood urea figure of 200 to 300 mg. per cent. has returned to normal limits after such relief—in fact, these high figures should be regarded as an indication for operations of relief. Radical operations, such as nephrectomy or prostatectomy, and extensive operations on the bladder, should be postponed till the blood urea has fallen below 50 mg. per cent. Azotaemia following operation is amenable to treatment if the figure does not rise above 200 mg. per cent. or does not remain too long at this height; it can be prevented by enforcing a low protein diet, and inducing moderate diuresis by such mild diuretics as Evian water. The importance of such preliminary operations as suprapubic drainage or the use of an indwelling catheter before radical operations is emphasized. Blanc adds that the severe regime necessary for medical cases of renal disease is best conducted in hydropathic institutions, but the possibility of a surgical condition must be excluded.

6. Non-tuberculous Haemoptyses.

H. TECON (*Rev. Méd. de la Suisse Romande*, September 10th, 1929, p. 589) calls attention to the considerable proportion of sputa examined for the tubercle bacillus with negative results. Of 800 sputa when this bacillus could not be found, *Spirochaeta bronchialis* was detected in 6 per cent. of the cases, a penicillium in 0.4 per cent., and other mycoses in 0.7 per cent. The author remarks that this is equivalent to 71 cases with infection other than the tubercle bacillus in 1,000 cases suspected of tuberculosis—a by no means negligible proportion. He concludes that in every case of haemoptysis where the tubercle bacillus is not detected by several repeated examinations a full bacteriological investigation of the sputum should be demanded. He defines seven principal types of non-tuberculous haemoptyses: cardio-vascular, cancerous, syphilitic, influenzal, hydatid cyst, bronchial calculus, and parasitic, including infections by spirochaetosis and various moulds. Each type is dealt with in turn and the etiological, symptomatic, and diagnostic features are considered. The importance of recognition of the last type is stressed and a more detailed description of it is given. Several cases are described in which a diagnosis of tuberculosis had been made on account of haemoptysis and other highly suggestive features, although tubercle bacilli had never been found in the sputum; more thorough examinations of the sputa revealed the presence of sporotrichosis, actinomycosis, or aspergillosis. Tecon adds that *x*-ray examination of the chest may help, and when the results are atypical of tuberculosis it becomes all the more important that a thorough search of the sputa be made for other forms of infection.

7. Septic Sore Throat.

D. J. DAVIS (*Journ. Amer. Med. Assoc.*, September 28th, 1929, p. 978) remarks that the present status of the epidemiology of septic sore throat is much the same as it was twenty years ago. Outbreaks are rare, but occasionally occur. Modern methods of pasteurization and the careful supervision of certified milk products, as well as new methods of identifying *Streptococcus epidemicus*, which seems to be the specific cause of the disease, should do, and possibly have already done, much to prevent epidemics. Studies of recent epidemics indicate that the usual if not the only route of transmission of the streptococci is from a human being to the teat and udder of a cow, where they rapidly multiply and then pass out into the milk directly to the throat of the consumer. Strains of *Streptococcus epidemicus* yield a specific soluble toxin which differs somewhat from the toxin of the scarlet fever streptococcus.

8. Ringworm of the Adult Scalp.

G. MASSIA and J. ROUSSET (*Ann. de Derm. et de Syph.*, August, 1929, p. 828) publish brief records of 23 cases of ringworm in adults. In 19 of these the parasite was one of the varieties of trichophyton, chiefly *T. violaceum*; in the remaining cases the parasite was the *Microsporon audouini*. Ringworm in the adult is comparatively rare, especially if those cases which persist from early childhood are excluded. In the microsporon cases (women with menstrual irregularities) the authors suggest that some endocrine deficiency may explain the susceptibility to ringworm.

Surgery.

9. Total Cystectomy for Bladder Carcinoma.

ENUMERATING the various groups of carcinoma of the bladder, E. BEER (*Annals of Surgery*, November, 1929, p. 864) states that there is one in which the trigone is so extensively involved that the ureters cannot be saved, and both have to be severed. In addition, many of these cases have extensive involvement of the vesical neck, so that the infiltrating growth involves half or more of the sphincter area and has invaded underlying tissues, particularly the adjacent prostatic tissues in the male. Four methods of treatment have been applied to these cases: suprapubic cystotomy; suprapubic cystotomy with electro-coagulation; suprapubic cystotomy with the introduction of radium deep into the growth; and total cystectomy with partial prostatectomy. The first two are usually little more than palliative, and only a few cases have been definitely cured by the third method. Beer draws the following conclusions from a review of the literature regarding complete cystectomy: the mortality is high unless the operation is performed in two steps; there is a definite mortality following bowel transplantation of the ureter; many patients have been relieved and have remained well for several years after the operation. The disposal of the ureters is the main problem because, wherever they are transplanted, attacks of pyelonephritis and secondary hydronephrosis are liable to occur. From personal experience Beer believes that the mortality of extraperineal cystectomy with partial prostatectomy is not prohibitive, and that it can be performed in one step by implanting the ureters into the skin without undue risk to the kidney; although patients must wear an apparatus for collecting the urine, they are much relieved, and may possibly be enabled to work. Eight cases are reported with only one operation death, and in this patient the ureters were obliquely transplanted into the sigmoid. In the remaining seven cases total cystectomy was immediately followed by implantation of the ureters into the iliac fossae. In all the cases the operations were performed in one step. The technique, which Beer does not consider difficult, is described. Of the surviving patients, one lived for five years, one for nine months, and one with leiomyosarcoma for over two months. Four patients are still alive four years, one and a half years, seven months, and six months respectively following the operation. The author adds that Federoff has attempted total cystectomy in females by beginning with an extirpation of the urethra, which is tied off after free dissection up to the neck of the bladder. The bladder is secondarily removed from above.

10. Thrombo-angiitis Obliterans.

M. E. BARRON and H. LINENTHAL (*Arch. of Surg.*, October, 1929, p. 735) describe thrombo-angiitis obliterans as a general disease which may attack any part of the vascular system; it may involve the blood vessels of the brain, neck, thorax, and abdomen, and not the blood vessels of the extremities only, as has sometimes been supposed. The symptoms are characteristic of the vessels involved. A lesion affecting the arteries of the brain may cause hemiplegia; if the coronary vessels are involved symptoms of coronary thrombosis or angina pectoris may ensue. A review is given of 34 cases of thrombo-angiitis obliterans occurring in persons under the age of 50, and therefore not of the "arterio-sclerotic age." It was found that the disease is slow and insidious in onset and may be of many years' duration. Since the vessels are slowly occluded, there is an opportunity for a collateral circulation to be established, and nutritional disturbance may not occur for several years in the parts involved. The process in the arterial tree does not spread by extension from a single focus, but may occur at different levels in an artery, and in various vessels at different periods. It is probable that the disease attacks the larger vessels first, and later obliterates the arterioles and capillaries, gangrene not occurring as a rule until late in the disease. The ability of the arteries to produce new and larger collaterals is often the deciding factor whether or not a patient will lose part of the body; the main arterial channels may be totally occluded without the part becoming gangrenous. The veins present a condition similar to that of the arteries, and a superficial phlebitis is fairly common in cases of thrombo-angiitis obliterans. A fresh clot is first noticed in the vein; it is made up of polymorphonuclear leucocytes, lymphocytes, mononuclear leucocytes, wandering cells, red corpuscles, and, later, foreign body giant cells are seen. The inflammatory cells invade the intima, media, and adventitia, and in the process of healing the vein, artery, and nerve are bound together by the newly formed inflammatory tissue, which soon becomes well organized. The inflammatory process keeps repeating itself in various vessels at various levels and at different times, so that the vessels are slowly occluded. The fact that patients have sometimes had symptoms for as long as twenty years proves the chronicity of the inflammatory process.

11. Compensation Treatment of Scoliosis.

A. STEINDLER (*Journ. Bone and Joint Surg.*, October, 1929, p. 820) maintains that the compensation treatment of scoliosis should aim at realignment of the trunk and body as a whole by means of compensatory secondary curves developed systematically in the adjacent sections of the spine. After body balance has been restored the musculature must be brought to a point of full control of body posture in order to maintain realignment, the degree of mobility or relaxation of the non-scoliotic sections imparted by the treatment being conditional upon the state of the muscles of the back. Except for congenital and traumatic cases of scoliosis, the skeletal parts of the spine play only a secondary part in producing the deformity, the primary changes being those of the muscular and ligamentous apparatus of the spine. Structural scoliosis in cases of the heavy, stocky type which have passed the period of rapid growth is sometimes spontaneously arrested under the development of secondary or counter curves; compensation treatment should follow this natural method rather than the method of forcible correction. Treatment should aim at the mobilization of sections of the spine to produce counter-curves and rearrange the body balance; stabilization by adequate mechanical support; and also muscle development and education to maintain the balance so regained. Compensation treatment is found to be adequate in cases of functional and postural scoliosis, which are about 10 per cent. of the whole number; in structural scoliosis of the habitual type and mild and moderate degree of rotation or lateral deviation, about 35 per cent. of the total; in paralytic scoliosis of the milder type; in some cases of congenital scoliosis; and in early or late rachitic scoliosis of moderate degree. Compensation treatment is a valuable aid preceding operative fusion. A large number of cases fused by the Hibbs method showed a subsequent break or pseudarthrosis formation in the dorso-lumbar level, due to the excessive strain caused by the "overhang" in non-compensated curves; this number included more severe paralytic cases which were still capable of passive realignment by compensation. Compensation treatment fails in the severest types of habitual scoliosis, in most cases of congenital scoliosis, and in the more severe types of paralytic and rachitic scoliosis.

12. Ptosis of the Colon.

K. H. AYNESWORTH (*Amer. Journ. Surg.*, September, 1929, p. 358) considers that ptosis of the ascending colon is congenital; he defines the following three types. In spastic colon this part of the intestine is smaller than normal; it is contracted, the musculature is thickened, the haustrations are small, and colitis results. The second type is a dilated colon with marked stasis, and a frequently dilated and defective ileo-caecal valve. The third type includes ptosis of a normal colon in younger patients, and those minor degrees of ptosis in which stasis will develop if treatment is not undertaken. The symptoms of right coloptosis are indigestion, constipation, and lassitude, with chronic right-sided abdominal pain, and in women menstrual irregularities. The pain in the right lower abdominal quadrant is irregular, chronic, and recurrent, but rarely severe; it is frequently mistaken for that due to chronic appendicitis. Pain may, in other cases, occur in the epigastric region and simulate that of a duodenal ulcer, coming at varying intervals after food. The onset of this pain is synchronous with the filling of the right colon from the ileum. In rare cases there may be pain in the region of the gall-bladder or in the right kidney region. The patients suffering from coloptosis are usually neurotic, due to the effect of stasis, and they often suffer from psychasthenia or some allied neurosis. The chief complications are colitis, pyelitis, indigestion, constipation, neurosis, and diarrhoea. The treatment should be medical in the early stages; if unsuccessful it must be followed by surgical treatment, colopexy by the Waugh technique being the operation needed to restore the displaced colon to the normal position.

13. Colles's Fracture.

E. J. GARVIN (*Med. Journ. and Record*, October 16th, 1929, p. 432) discusses the treatment of Colles's fracture as conducted in the Misericordia Hospital of Philadelphia, and describes the methods adopted in several other institutions. Statistics in 50 cases showed that the condition occurred almost equally in both sexes, females tending to be affected chiefly in childhood and old age, while males suffered mostly between the ages of 20 and 45, during the period of greatest industrial usefulness. Impaction occurred in eight cases, and in 20 per cent. of the total cases the styloid process of the ulna was also fractured. On admission an attempt at reduction was made without anaesthesia, and a splint was applied at once in the absence of any displacement. If unsuccessful, reduction by hyperextension, traction, ulnar abduction, and forced flexion with manipulation was carried out under N_2O anaesthesia, and a splint applied. On the following day an *x*-ray examination was made to determine the position of the fragments and the condition of the carpal arch; if satisfactory, the limb was put up in splints, or a plaster cast, for three to four weeks, with frequent change of dressing. Light massage was commenced at the end of the first week, with passive movements of the fingers at the end of the second week, and of the wrist at the end of three weeks. Garvin adds that after removal of the splints supervised physiotherapy should always be employed. From a consideration of various other methods adopted the moulded plaster cast seemed to be the best retention apparatus, being capable of more comfortable adaptation with the provision of the requisite amount of flexion and ulnar abduction for each individual case.

14. Surgical Treatment of Intestinal Tuberculosis.

L. BONAFE (*Presse Méd.*, September 18th, 1929, p. 1213) records seventeen cases of phthisis complicated by intestinal tuberculosis which were treated by abdominal operation. The tuberculous process had been more or less stabilized in each case by previous sanatorium treatment, but some of the lesions were extensive. In eight cases the operation was limited to laparotomy with or without appendicectomy; in three cases simple anastomosis was effected, and in six cases intestinal resection was performed. No other methods of treatment were attempted. In four of the eight laparotomy cases the lesions were found to be so extensive as to be regarded as incurable; two patients, however, did surprisingly well, and were subsequently classed as cured. Four out of these eight patients recovered completely, two were improved, and two died afterwards. Anastomosis resulted in one cure, one improvement, and one failure. Resection was attended by success in four cases; one patient improved temporarily, but relapsed and died later with laryngeal complications. In the sixth case the disease was too advanced, and the patient died a fortnight after the operation. In all there were nine clinical cures and three improvements amongst the seventeen cases. The author suggests that abdominal tuberculosis will more and more pass into the realm of surgery. In no instance was any extension of the pulmonary condition observed to follow the operation.

Therapeutics.

15. Vaccine Treatment of Soft Chancre.

A. F. LASSEN (*Ugeskrift for Laeger*, September 26th, 1929, p. 817) has conducted investigations at the Rudolf Bergh Hospital in Copenhagen with a vaccine prepared from dead cultures of Ducrey's bacillus. He gave this vaccine in increasing doses by intravenous injection, being guided by intradermal reactions provoked by its injection previously into the epidermis of the upper arm. The intradermal reaction was always negative in patients not suffering from a soft sore, and the degree to which it was positive varied with the stage of the disease, being slightest when a soft sore had just been acquired, more violent when a bubo had supervened and perforated, and most violent in cases of reinfection. Lassen states that the capacity to respond with a positive reaction persists probably for life, or at any rate for many years after recovery from the infection. The intradermal reaction usually becomes negative after the fourth intravenous injection of the vaccine given in increasing doses, and it again becomes positive some ten to fifteen days after the completion of these injections. The more violent the intradermal reaction the more effective and rapid was the therapeutic action of the intravenous injections. On the other hand, quite new cases of soft sore, in which the intradermal reaction was not yet positive, proved to be refractory to intravenous injections. These should therefore be deferred till the patient has been sensitized by his infection, and this does not usually occur till eight to twelve days after the first appearance of the sore. After giving details of the technique of the injections, the author, who had treated eighteen cases up to the end of February, 1929, states that the results were beyond his expectations. Large and fluctuating buboes, seemingly on the point of perforation, lost their inflammatory character in two or three days, and shortly afterwards disappeared completely, while the primary sore cleared up under a boiled water compress. The results thus achieved were superior in every respect to those following the conventional, non-specific treatment with incision of the suppurating buboes. While the author recommends such vaccine treatment in every case complicated by buboes, whatever their duration, size, or condition, he does not consider such specific treatment necessary or advisable in every uncomplicated case of soft sore, for which local treatment is often adequate.

16. Levulose in Diabetic Acidosis.

O. PUCSKO (*Münch. med. Woch.*, October 18th, 1929, p. 1755) has investigated the action of levulose administered by the mouth and by intravenous injection on the ketone bodies in the blood and urine of severe cases of diabetic acidosis. After the administration of levulose, either alone or succeeded, preceded, or combined with insulin, quantitative estimations of the amounts of ketone bodies in the blood and urine were made over a period of several days. Single doses of levulose by itself exhibited no appreciable action, but if repeated on several days a slight fall of the ketone body content was manifested; when insulin was also administered a much better result was attained. The intravenous dose of levulose employed was 20 c.mm. of a 50 per cent. solution, and 10 grams per dose if administered by the mouth. Insulin was given subcutaneously in doses of 20 to 40 units, but for intravenous injection the dose did not exceed 20 units. Clinical notes are given of four patients suffering from severe ketonaemia and ketonuria in which the acidosis was favourably affected by the intravenous injection of levulose combined with insulin treatment; some of the patients had already been treated with insulin and were found to be in some degree refractory. The author remarks that intravenous doses of dextrose generally show a more rapid action on the ketone bodies than levulose, but by the addition of levulose the diminution of the quantities of ketone bodies by dextrose will be maintained. Levulose given by the mouth and followed by insulin injections removes the ketone bodies, and will reduce the sugar in the urine to almost *nil*, but the action takes place more slowly than when it is injected intravenously.

17. Administration of Pure Oxygen in Cardiac Failure.

VARIOUS observers have suggested that death following pulmonary embolism is due to reflex failure of the heart. Attempts have therefore been made in human patients and animals to maintain the activity of the heart by inhalation of oxygen so long as there is any circulation in the lungs. G. LOTHEISSEN (*Zentralbl. f. Chir.*, October 12th, 1929, p. 2563) reports a case in which the typical symptoms of pulmonary embolism developed ten days after an uneventful appendicectomy. As soon as oxygen was administered the pulse improved; camphor and strychnine were also injected, but when the supply of oxygen was discontinued the patient relapsed and became blue and pulseless again. The administration of oxygen was therefore continued for three days; at the end of this time cyanosis did not return and the pulse remained good. The patient made a slow but complete recovery, and was discharged seven weeks after the operation. Lotheissen suggests, therefore, that patients with pulmonary embolism should be immediately treated with pure oxygen, and that this measure, combined with artificial respiration and heart massage, might also be useful in other forms of reflex inhibition of the heart such as that which follows electric shock.

18. Potassium Sulphocyanate in Hypertension.

R. S. PALMER, L. S. SILVER, P. D. WHITE, W. BLOOMBERG, and R. G. HAHN (*New England Journ. Med.*, October 10th, 1929, p. 709) report the clinical use of potassium sulphocyanate in 59 cases of hypertension. The majority of the patients were between the ages of 50 and 70, and were cases of essential hypertension, many showing such secondary effects of hypertension or of age as hypertensive heart disease, renal changes, congestive or anginal failure, and arterial disease. The usual therapeutic procedure was the administration of 1½ grains of potassium sulphocyanate in one drachm of water three times a day for the first week, twice a day for the second week, and once daily for the third and fourth weeks. A fall of 30 mm. of mercury or more in the systolic pressure while under treatment was regarded as indicating a definite effect, and on this basis the cases were divided into two groups: those showing such a definite response and those in whom the fall in pressure was less than 30 mm. of mercury. In 25 cases (42.4 per cent.) there was a good reaction to the treatment, while in the remaining 34 cases (57.6 per cent.) the result, though possibly favourable, was not so marked. Of the eight cases showing the most marked fall in systolic pressure (40 to 70 mm. of mercury), five were definitely cases of essential hypertension, and the other three had arterio-sclerotic and hypertensive heart disease. Although a few of the patients complained of weakness, anginal pain, or precordial distress while taking the salt, no definitely toxic effects were noted, but the treatment should be started cautiously, since unfavourable symptoms may follow in patients with renal changes or coronary sclerosis. The authors recommend trial of potassium sulphocyanate in patients suffering, or likely to suffer, from the effects of hypertension.

19. Treatment of Blackwater Fever.

J. FORBES (*Kenya and East African Med. Journ.*, September, 1929, p. 152), inspired by Professor MacLean's article on the treatment of gastric ulcer by combined alkaline carbonates (*Journal*, April 14th, 1928, p. 619), applied the method in the treatment of blackwater fever as follows. As soon as haemoglobinuria develops in a case of malaria under treatment, all food is stopped; boiled water alone is given until the urine has been clear for three days and is alkaline in reaction. Alkalis are administered according to MacLean's formula (sod. bicarb. 2½ oz., calc. carb. 5 oz., mag. carb. pond. 5 oz., bismuth oxycarb. 10 dr.), and one flat teaspoonful of the mixture is given every two hours in water from 6 a.m. to 10 p.m., when a double dose is administered. Absolute rest is essential. The windows must be open to ensure pure air, since much of the blood is destroyed and its oxygen-carrying capacity is reduced. Three or four doses of calomel (about 0.75 grain), at intervals of half an hour, are very useful. An enema of soap and water is given at the outset, and enemata of a weak solution of potassium permanganate twice daily. If the temperature falls and remains down no quinine is given at all, but sometimes a temperature resembling that in subtertian fever continues, and parasites may be found in the blood. In such cases small doses of tincture of cinchona (1 drachm three times a day) should be given. As improvement takes place a careful start with milk may be made, and the amount rapidly increased if the urine is neutral or fairly alkaline. A few days later the diet may be increased by jelly, fruit juice, and oatmeal porridge.

Anaesthetics.

20. Colonic Anaesthesia.

J. T. GWATHMEY (*Journ. Amer. Med. Assoc.*, August 10th, 1929, p. 447) reports his experience of 5,000 cases anaesthetized by the introduction into the colon of ether in olive oil. Experiments on animals have shown that if 0.01 gram of atropine per gram of body weight is given previously, full surgical anaesthesia can always be assured; it is completely controllable if the correct dose is administered, and can be promptly terminated by lavage. Colitis is unknown where no previous inflammation has existed. The special advantages of the method are that there is no psychic shock, less bleeding than with ordinary anaesthesia, and the recovery is uneventful, without nausea. The ether is really outside the body until it evaporates and is absorbed; Gwathmey gives charts showing the evaporation rate. He does not consider renal, pulmonary, or cardiac conditions contraindicate its employment, but all pathological conditions of the lower bowel, including colitis, haemorrhoids, and fistula, should bar its use. Special indications for the method are alcoholism, obesity, brain surgery, oesophagoscopy, suspension laryngoscopy, bronchoscopy, hyperthyroidism, and operations on the head, neck, and chest. During colonic anaesthesia the pulse rate, respiratory rate, and blood pressure are said to be lower than under ordinary conditions. Control of anaesthesia during the operation can be effected by placing a towel over the face to ensure rebreathing; the occasional use of supplementary open anaesthesia; and the introduction into the rectum of a further dose of 65 or 75 per cent. ether in oil, about 1 oz. for each extra hour of anaesthesia required. The night before the operation a light supper of tea and toast is given, followed after two hours by two tap-water enemata with an interval of twenty minutes between them, and the administration of 10 grains of barbital. Two hours before the operation a low clear-water enema is given, and 1/8 gram of morphine is injected subcutaneously; a 10 grain chlorbutanol suppository is inserted deeply, and half an hour later a subcutaneous injection of atropine gram 1/150 is given. Rectal instillation of the "retention enema" is then begun, the catheter and funnel being first filled with warm oil to exclude air; the retention enema mixtures in use are: ether 4 oz., olive oil 2 oz., paraldehyde 2 drachms; or ether 5 oz., oil 2½ oz., paraldehyde 2 drachms; or ether 6 oz., oil 3 oz., paraldehyde 2 drachms. Forty minutes before operation a final enema is given consisting of ether 3 oz. and olive oil 1½ oz., ten minutes being taken for its administration; absolute quiet must then be assured for the patient. Danger signals are cyanosis, dulled corneal reflex, and stertor; support of the lower jaw will usually correct the last-named. Summarizing his results, Gwathmey states that 65 to 75 per cent. ether in oil is non-irritating; the method can be used with safety where a cautery is to be applied in the region of the mouth; there is an absence of any "pain reflex" when the patient recovers; and sometimes there is actual amnesia of the fact of operation.

21. **Intratracheal Ethylene-Oxygen Anaesthesia.**

H. R. GRIFFITH (*Canadian Med. Assoc. Journ.*, September, 1929, p. 294) has used this method successfully for more than four years in a series of 1,200 cases of nose, throat, and ear operations, and of thyroidectomies. The ages of the patients ranged from 14 months to 70 years. The preliminary hypodermic injection of 1/4 grain of morphia and 1/50 grain of hyoscine is advocated, but not insisted on, especially in the case of children. After anaesthesia has been induced with nitrous oxide-oxygen, followed by a little carbon dioxide, ethylene, and ether, the face mask is removed, the head is thrown back, and the larynx is exposed quickly with a suitable Jackson speculum. A silk or lisle catheter of the proper size—F16–F18 for infants, up to F32—is introduced and the end pushed down to about 3 cm. above the bifurcation of the bronchi; this will be about 22 cm. from the teeth in the average adult. The ethylene is passed into the catheter by way of a small rubber bag, into which the patient should do a good deal of rebreathing. The possibility of explosion has to be constantly kept in mind, though the author has had no accident. He observes the following precautions. The Foregger "metric" and the "safety" machines are used, both of which contain water. In order that the gas may flow only over a wet surface a few drops of water are introduced into the rubber tubing and the rebreathing bag. The anaesthesia is finished, as started, with nitrous oxide and a little carbon dioxide. No cautery or other open flame or spark is permitted in the operating room during the administration of ethylene. The advantages claimed are: (1) the respiration is always under control, with no possibility of obstruction: (2) no hypersecretion of mucus occurs, as is the case with ether: (3) there is an immediate response to carbon dioxide or oxygen stimulation when necessary; (4) more satisfactory relaxation ensues than with nitrous oxide; (5) the patient wakes immediately after the operation and nausea seldom occurs; (6) there are no pulmonary sequels. The author considers this almost the ideal anaesthesia for small children.

22. **Ether Anaesthesia in Children.**

E. v. d. PORTEN (*Schmerz Narkose-Anaesthesie*, August 15th, 1929, p. 167) remarks that though there are no specialists in anaesthesia in Germany, everyone who has any experience of anaesthetics knows that the course in children is different from that in adults. Ether anaesthesia in children is attended with certain dangers owing to the rapidity with which they go deeply under the anaesthetic: the pupils rapidly become dilated and fixed, and the respiration fails. The following precautions should therefore be taken. As soon as the stage of excitement is passed there should be a considerable reduction in the frequency with which the drops are administered. The maximum constriction of the pupils preceding the dilatation in which no reaction takes place should be absolutely avoided in children, though in adults this stage may be reached with impunity. The stage of excitement is followed by an intermediate stage in which the corneal reflex disappears on one side but is still just present on the other. This intermediate stage has the advantage of being readily detected in children, and is not attended by danger at any age; it is particularly suitable for children in all operations except those on the peritoneum, in which the anaesthetic must be pushed. Children above the age of 4 years should be given an injection of morphine and atropine before ether anaesthesia. In conclusion the author states that girls about the age of puberty require a relatively large dose of the anaesthetic, and special care should be taken that such patients are kept in the intermediate stage.

23. **Spinal Anaesthesia.**

W. BOCTOR (*Journ. Egyptian Med. Assoc.*, September 23th, p. 122) records a series of 620 cases of spinal anaesthesia; a mixture of stovaine and caffeine was used, and no preliminary morphine injection was given. The Trendelenburg position was adopted in every case. As regards the blood pressure, in 44 cases this was unchanged, in 16 there was a rise, and in the rest a slight fall occurred. Most authorities have stated that it is not safe to use spinal anaesthesia when the blood pressure is below 100 mm. of mercury, but the author used it successfully in fourteen cases where the blood pressure was between 80 and 50. He remarks that it is not so much the actual fall as the sudden fall of blood pressure which is dangerous. As regards complications, the occurrence of nausea and vomiting, early or late, was noted in 50 cases; retention of urine in 91, of which in 31 there was some form of bladder disease; headache in 93, usually easily controlled by simple remedies, but in 4 cases persistent and severe; but there were no cases of backache or paralysis, and no death. In 22 cases a whiff of chloroform was required; in 30 cases the anaesthetic had to be supplemented, and in 19 no anaesthesia was produced by the spinal injection.

Obstetrics and Gynaecology.

24. **Haemorrhage from the Corpus Luteum.**

A. MUHL (*Zentralbl. f. Gynäk.*, September 14th, 1929, p. 2350) suggests that the clinical diagnosis of intra-abdominal haemorrhage from a corpus luteum may be simplified by examination of the urine by the Zondek-Aschheim test for pregnancy; a negative test will exclude extrauterine pregnancy. He records two cases of intra-abdominal bleeding from a corpus luteum in patients aged 23; in one the clinical diagnosis was acute appendicitis, and in the other the presence of a small cystic tumour in the postero-lateral fornix led to laparotomy for a supposed extrauterine pregnancy. In both cases the abdomen contained considerable amounts of blood, which was traced to a corpus luteum. Microscopical examination of both tubes and both ovaries (which has been said to be essential if other sources of bleeding than the corpus luteum are to be excluded in these cases) was not possible, but amenorrhoea was absent in the case-history of both patients, and one was a virgo intacta. In both cases the acute symptoms dated from the height of the premenstrual phase of the cycle.

25. **Auto-Blood Infusion in Gynaecology.**

LILIAN K. P. FARRAR (*Surg., Gynecol. and Obstet.*, October, 1929, p. 454) commends auto blood infusion in clean pelvic operative emergencies associated with haemorrhage, and mentions the necessity of preliminary training of the medical and nursing staff of the hospital in the technique. Among the advantages claimed for the method are the immediate restoration of blood to the circulation without the delay entailed in finding a suitable donor, the avoidance of any reaction due to incompatibility, and the ease with which it can be performed. In a sterile graduated suction bottle 10 c.cm. of sterile 2 per cent. sodium citrate solution is placed; blood is drawn directly from the abdomen into this to the 100 c.cm. mark. The bottle is then removed and replaced by another, and suction again commenced. The 100 c.cm. of citrated blood in the first bottle is then poured through twenty thicknesses of gauze wet with sterile normal saline solution lying on the top of a sterile funnel in a flask standing in a basin of hot water; 50 c.cm. of sterile normal salt solution are poured over the blood, which is then covered to prevent aeration and allowed to filter. The blood thus collected is introduced by the gravity method into the median basilic vein in the arm: 250 to 300 c.cm. can usually be given. The author remarks that the method does not interfere with the operation if the staff has been trained in the technique. It cannot be adopted if the blood is stagnant or clotted, or if there is any suspicion of infection in the pelvis or abdomen. The 2 per cent. sodium citrate solution keeps indefinitely in sealed sterile ampoules, and 10 c.cm. used with each 90 c.cm. of blood prevents coagulation; at least five times as much sterile normal salt solution as sodium citrate solution should be used.

26. **Acacia in Obstetrical Shock.**

CONTRARY to the opinion of certain authors, L. M. RANDALL (*Journ. Amer. Med. Assoc.*, September 14th, 1929, p. 845) considers that there is no fundamental difference between obstetrical and surgical or traumatic shock, and that the symptoms and treatment are the same. One of the outstanding features of shock, as a rule, is collapse due to lack of fluid in actual circulation. Keith and others have pointed out that nature's first reaction to shock is to supply fluid, and not erythrocytes, to the depleted circulation. The intravenous injection of solutions of sodium chloride and of dextrose is not entirely satisfactory, since they only temporarily increase the blood volume; gelatin has been discarded because of the difficulty of securing sterile solutions. Bayliss, experimenting with acacia, found that a 6 per cent. solution was entirely innocuous, and was capable of raising the blood volume and maintaining it. This method has been much employed in the Mayo Clinic, and Randall strongly advocates its use. The need in shock is for fluid that will remain in the circulation, and acacia fulfils all the requirements for intravenous treatment of shock, except the provision of erythrocytes. It increases the volume of plasma and blood, and keeps it increased until the normal fluid-regulating mechanism of the body is restored. Randall believes that in many cases life has been saved by its early use and by the postponement of operative procedures until the initial shock has been controlled; he adds that, as a preventive of shock, it is wise to give an injection of acacia solution in cases of fatigued or debilitated patients when obstetrical operations are to be performed. Proper preparation of the solution is emphasized, and a method is described. The injection is performed much in the usual way. It is best to use a needle

of large bore or a cannula; the gravity method of administration is good, and has the advantage of simplicity. From 25 to 40 c.cm. is given each minute, until from 500 to 1,000 c.cm. have been injected. Since shock is often accompanied by or is due to haemorrhage, treatment must include haemostasis. Besides these measures, heat should be applied and the head of the patient be lowered. Morphine may be given if the patients are restless, and stimulants, such as epinephrine and caffeine, are often indicated. Two illustrative cases of shock in obstetrical patients are recorded to demonstrate the efficacy of acacia in this condition.

27. Pyelitis in Pregnancy after Nephrectomy.

C. COLOMBINO (*Ann. di Ostet. e Ginecol.*, September 30th, 1929, p. 1114) discusses the dangers and treatment of pyelonephritis occurring in pregnant subjects who possess one kidney only. He points out that pyelonephritis occurs in approximately 1 per cent. of pregnancies, and the mortality of the acute condition is very small, although Dosza has recently reported a series of one hundred cases with four deaths. Recent studies have shown that serious sequels of pyelitis gravidarum are more frequent than was formerly supposed; they consist in occasional hydronephrosis and ureteral stenosis, but more often in the production of a contracted pyelonephritic kidney, in which a granular kidney not unlike that familiar to physicians is associated with infection both of the renal parenchyma and of the ureteral and periureteral zones. For these reasons, when the patient with pyelitis possesses a single kidney only, the risk of medical treatment (in spite of the success which as a rule follows in the disease) is too great, and speedy termination of the pregnancy is the only prudent course. Colombino records the case of a woman, aged 23, who had had two normal pregnancies and labours. A third pregnancy was associated with increasing and intractable pain in the left iliac fossa; a tumour palpable to the left of the tenth dorsal vertebra was proved to be the displaced left kidney by the fact that on cystoscopy the left ureter emptied more slowly than the right, but much more quickly when pressure was exercised on the abdominal swelling. The left kidney was removed and proved microscopically normal. The patient was readmitted to hospital three weeks after the operation, in the sixth month of pregnancy, with signs and symptoms of acute right pyelonephritis, which abated rapidly after induction of labour by Braun's bag.

Pathology.

28. The Sedimentation Test in Leprosy.

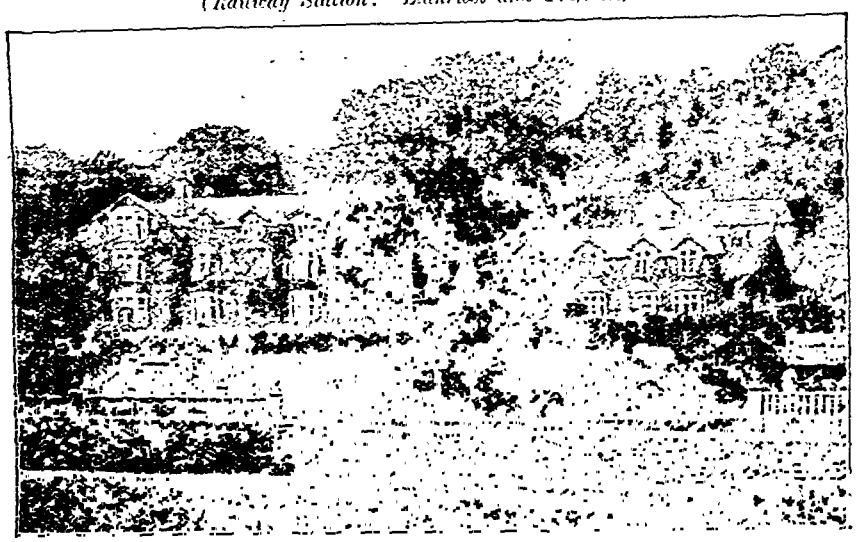
E. MUIR (*Indian Med. Gazette*, September, 1929, p. 488) suggests that the sedimentation test is a valuable means of testing the efficiency of drugs used in the treatment of leprosy, and is also a useful aid in diagnosis and prognosis. A technique is described which renders it possible to test a large number of blood samples fairly accurately and rapidly. An all-glass 2 c.cm. syringe receives 0.3 c.cm. of a 5 per cent. solution of sodium citrate in distilled water, and then 1.2 c.cm. of blood is drawn into it from a vein and thoroughly mixed; the mixture is then expelled into a clean test tube. If there are several patients to be tested a similar procedure is adopted with each, and the test tubes are labelled and placed in order in a rack. Sedimentation is carried out in 300 mm. pipettes graduated from above downwards from 0 to 100 with a space of 3 mm. between each mark. The content when filled up to 0 approximates 1 c.cm., but a variation of 0.05 c.cm. makes no appreciable difference in results. These pipettes are placed upright in a rack with their points inserted into holes in rubber corks to prevent the mixture escaping. A 10 c.cm. syringe is attached by a rubber tube to the upper end of a pipette, the point of which is inserted into one of the test tubes; the blood-citrate mixture is drawn up to the 0 mark and the pipette replaced in the rack. The other pipettes are dealt with in the same way. After one and a half hours, and again after two and a half hours, the top levels of the erythrocytes are read, the average of the two readings being taken as the sedimentation index (S.I.). Muir states that as a rule the S.I. in the different stages of leprosy increases in direct proportion to the number of bacilli in the body, and it is also a criterion of the reaction phase directly proportionate to the degree and extent of the reaction. The effect of a given dose of medicine or injection upon the S.I. affords an indication whether the next dose requires increasing or diminishing, or at what interval it should be given. A remedy which does not raise the S.I. is unlikely to be effective in eliminating the leprous infection.

29. The Acid-Base Equilibrium of the Blood in Acute Rheumatism.

THE theory of the infective origin of rheumatism, now commonly accepted, raises the question whether the causal organism may be one that produces an acid toxin. In order to obtain evidence for or against this hypothesis, L. G. PARSONS and S. H. EDGAR (*Arch. Dis. in Childhood*, October, 1929, p. 291) have investigated the acid-base balance of the blood in rheumatism. Normally the *p*H of the blood is extremely constant, but certain pathological conditions can induce an acidosis or an alkalosis. Usually, however, any change tending to occur is speedily regulated by alterations in the excretory systems, which neutralize the disturbing effect and keep the *p*H constant. This is not always so, and should a point be reached where the regulating mechanism is unable to cope with the disturbing factor—as, for example, in diabetes, where the production of non-volatile acids is continuous—the *p*H will be altered and an abnormal figure obtained. To ascertain the acid-base balance, or equilibrium, of the blood two estimations are necessary—namely, of the *p*H and the carbon dioxide content. These tests were applied to the blood of 53 children, all of whom had received institutional treatment for a period of one to two years or even longer. The results showed that the acid-base equilibrium of children suffering from acute rheumatism, whether in the acute, convalescent, or quiescent stages of the disease, was normal. The authors conclude that there is thus no evidence in favour of the view that the symptoms of rheumatism are due to an excess of acid in the tissues, or that the rheumatic child is an "acid" child. As regards other factors, Edgar has investigated the variability in blood calcium in rheumatism, and his results support this conclusion.

30. The Bactericidal Power of Human Blood in Typhoid Fever.

R. VEGNI (*Lo Sperimentale*, September 10th, 1929, p. 351), as the result of observations on ten normal subjects and eleven patients with typhoid fever, aged from 14 to 41, came to the following conclusions. The blood of healthy subjects presents a considerable bactericidal action on the typhoid bacillus *in vitro*, this action ranging within wide limits. The blood of typhoid patients possesses a bactericidal power on the typhoid bacillus which is usually higher than that of the normal subject; this power shows an increase during the first stage of the disease, reaching its maximum in the second or third week, and then declining during defervescence and still more so in convalescence. When defervescence is delayed and the course of the disease is severe the bactericidal power shows only a slow decrease. A study of the bactericidal power of the blood does not appear to have any prognostic significance, since a high bactericidal value was found both in severe and mild cases. No relation was found to exist between the bactericidal power of the blood and the agglutinating properties of the serum. Vegni adds that in the study of the bactericidal power of the blood it is essential to use fresh blood which has been defibrinated.



31. The Reticulocyte Reaction in Anaemia.

J. WAHLBERG (*Acta Med. Scand.*, October 17th, 1929, p. 143) contributes a study of blood regeneration in simple anaemia, comparing treatment by liver diet, by iron and arsenic, and by hospital treatment without special therapy. The expectant treatment afforded an estimate of the patients' spontaneous power of regeneration. Of the 10 cases so treated over a period of several weeks, the haemoglobin percentage remained unchanged and the rise of red cell count was only slight. In 19 cases the effect of iron and arsenic was compared with that of liver diet. Iron and arsenic did not give better results than liver alone; of 15 cases, 9 responded favourably to liver; there was no difference observed between the effect of liver extract and whole boiled liver; in 3 out of 13 cases there was better reaction to liver alone than to iron and arsenic. The reticulocyte reaction in simple anaemia is dependent on and approximately proportional to the blood regeneration; at first it is inversely proportional to the red cell count, but is only marked when the red cell count is below 3 million, and was most marked in severe post-haemorrhagic anaemia during iron and arsenic treatment. The specificity of the reticulocyte reaction for pernicious anaemia is questioned; the greater reaction and the sudden start of the regeneration after the commencement of the liver treatment are accounted for by the lower red cell counts of these patients. The practical value of the reticulocyte reaction in simple anaemia, as in pernicious anaemia, is an early indication of commencing improvement.

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

ARTHRITIS. AMBULATORY TREATMENT.

Mobility and freedom from pain in crippling arthritis of the hip and knee even after shortening and contracture have occurred.

This is the special achievement of BELLE VUE SPA; secured by Hoefftcke's extension appliances, which maintain continuous extension by night and by day.

The appliance permits the patient to walk, and not only takes the body weight but replaces the normal state of compression of the leg by one of active stretching.

There is no other satisfactory way of combining movement with extension.

The method secures:

1. Extension without muscle loss inevitable when the patient is kept in bed.
2. Extension without the vascular stasis which occurs when a joint is kept at rest,

AND MOVEMENT WITHOUT PAIN.

The result is rapid reconstruction of the joint with astounding restoration of function in those advanced cases which have hitherto seemed hopeless and incurable.

BELLE VUE SPA is well equipped for auxiliary treatment by massage, electricity, diet, light, etc., and full advantage is taken of the tonic virtues of its chalybeate waters.

The strongest pure ferrous iron waters in the world.

NOT CONSTIPATING.

FREE FROM FERRIC SALTS AND OTHER IMPURITIES.

Close co-operation maintained with the patient's own practitioner.

Physician: HUGH WILLIAMS, L.R.C.P., L.R.C.S.(Ed.).

RUSCOL.

(Registered Trade Mark)

An Organic Compound of Bismuth and Birch Tar.

This Ointment has been found most successful in cases of Eczema, Erysipelas, Pruritus, and all Skin Diseases, either itching or inflammatory. PRICE 5/- lb.

ELIXIR EPHEDRINÆ CO.

Each fluid drachm (4 c.c.) contains Ephedrine Hydrochloride, ¼ grain (0.016 gm.), with Tinctures of Eriodictyon, Grindelia, and Piscidia.

Most useful and efficient for the relief of Bronchial Asthma, Whooping Cough, Hay Fever, Hypotonia, etc. Characterised by its negligible by-effects, prolonged action, and reliable therapeutic effect.

In 20 cases of Whooping Cough, relief from spasm and vomiting occurred in 18 of the patients.

PRICE: 4/6 per 8-oz. bottle; 16-oz., 8/-.

ELIXIR BROMO-VALERIAN CO.

An excellent Ca...lmative and Nerve Sedative, free from any ...disagreeable taste or odour.

Each ...fluid drachm (4 c.c.) contains:

Strontii Bromidi ... 5 gr. *Tinct.* Adonis Vernalis 5 m.
Tinct. Valer. Deodorat. 10 m. *Tinct.* Visci Alb. ... 5 m.

Useful for functional nervous affections, particularly in controlling epileptic seizures.

DOSE.—1 to 4 fluid drachms (4 to 16 c.c.) diluted. PRICE 5/- lb.

AROMATIC CASCARA.

An agreeable and physiologically active preparation almost devoid of bitterness, which represents the therapeutic virtues of Cascara Sagrada.

PRICE 6/6 lb.

Intestinal Disinfection

FLATULENCE AND ALIMENTARY FETOR

MANY conditions are associated with flatulence, some of which frequently give rise to embarrassment of distant organs.

Dyspepsia, catarrh and ulceration of the stomach and intestine, cancer, dysentery, and other diseases of the alimentary canal itself, neurasthenia, and diseases of the heart, liver and pancreas, to name only a few, may all be associated with flatulence and intestinal flatus.

Some of the diseases of the intestine, such as dysentery and cancer, are often also associated with horrible fetor of the evacuations.

The accumulation of flatus in the stomach and intestine is liable to embarrass the action of the heart and lungs, giving rise to dyspnœa, disordered action of the heart, faintness and even anginal attacks.

Both the flatulence and fetor are the result of abnormal fermentation and putrefaction of the contents of the alimentary canal; apart from treatment of the condition itself, it can be rationally controlled by the use of an efficient intestinal disinfectant. For this purpose, Kerol, the most potent germicide, being unabsorbed and non-toxic, is unsurpassed, and can be safely administered in sufficient amount to exert its germicidal action.

When the fermentation is located in the stomach, KEROL CAPSULES (Gastric) m. 3, should be administered: one or two may be given three or four times a day after meals.

When there is intestinal flatus and fetor, the keratin-coated KEROL CAPSULES m. 3, should be used, the dose being one to three after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

MESSRS. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Literature and supply for clinical trial obtainable from the manufacturers.

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

COPYRIGHT

ESTABLISHED 1793

DOCTORS

prescribe "ARDENTE"

because they know it is fitted from a wide range of distinct types—very inconspicuous—devoid of extraneous buzz—true-to-tone for conversation, music, church, theatre, public and school work. They also know that the guaranteed "Ardente" carries a genuine "after-sale-service"

Every important Medical Journal in the land has commended Mr. R. H. DENT'S world-famous aid for its efficiency and simplicity, and, if greater proof were required, it lies in the fact that

for their *DEAF* patients.

many DEAF DOCTORS use "ARDENTE"

"ARDENTE" STETHOSCOPE.—Mr. R. H. Dent also makes a stethoscope specially for members of the medical profession suffering from deafness, slight or acute. Many are in use, and excellent results are reported.

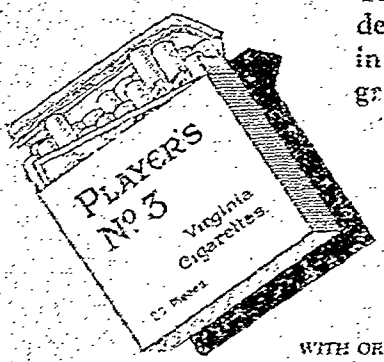
WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.



Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

Royal Dental Hospital of London

and LONDON SCHOOL OF DENTAL SURGERY (University of London), Leicester Square, W.C.

The POSTS of LECTURER on ANÆSTHETICS and BACTERIOLOGY to the above Institution are vacant. Members of the staff are eligible for these appointments. Candidates for the appointments are requested to send in their applications, accompanied by three testimonials, on or before January 25th, 1930, to the Dean.

Birmingham Union.

SELLY OAK HOSPITAL.

TWO CASUALTY OFFICERS (Male).

Applications are invited from fully qualified Medical Practitioners for the appointments of Casualty Officers (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 540 beds divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children, and Infectious Sections. There is a completely equipped Pathological Laboratory, also X-ray, Electro-therapeutic, Massage, and Sunlight Departments. Over 2,200 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that time.

The officers appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to them by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointments is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointments may be obtained from the Medical Superintendent, Mr. R. P. STANLEY KELMAN, M.B., F.R.C.S. (Eng. & Edin.) at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Wednesday, January 8th, 1930.

Union Offices, Birmingham. December 12th, 1929.

C. P. BEECH, Clerk to the Guardians.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

GYNÆCOLOGIST AND OBSTETRICIAN.

Applications are invited from fully qualified Medical Practitioners for the above appointment.

The Hospital accommodation is fixed by the Guardians at 926, divided into Medical, Surgical, Children's, Infectious, Gynæcological, and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments.

Candidates for the appointment must have had previous Hospital experience of a similar nature and be Fellows of the Royal College of Surgeons (England).

The scale of salary will be £700, rising by annual increments of £50 to a maximum of £1,000 per annum, and the salary of the successful candidate will be fixed within the scale according to experience and qualifications. Furnished quarters, rations, laundry, and attendance will be provided by the Guardians. Alternatively, a cash allowance will be paid if the officer appointed is non-resident. A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896.

The officer will be required to assist in the training and lecturing of nurses, and, should occasion arise, to attend at any of the other Institutions under the control of the Guardians.

Further particulars of the appointment may be obtained from the Guardians' Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

The University of Manchester.

Applications are invited for the post of LECTURER IN DENTAL HISTOLOGY. Stipend £50 per annum. Duties to commence as early as possible in the Lent Term, 1930. Applications should be sent not later than Friday, January 24th, 1930, to the REGISTRAR, from whom further particulars may be obtained.

Rossall School. — Some twelve

Open SCHOLARSHIPS for boys between the ages of 12 and 14, on March 1st next, value from £90 a year downwards, will be awarded by Examination, beginning March 4th, 1930. Boys examined at Rossall and in London.—Apply, THE BURSAR, Rossall School, Fleetwood.

Resident Medical Officer required

for LEEDS JEWISH [illegible] AL. Salary £100 per [illegible] Ample time for Post-graduate work.—Apply, Secretary, Herzl-Moser Hospital, Leopold Street, Leeds.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in January, 1930. Applications should reach the War Office not later than January 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January. They must be under 28 years of age on February 1st, 1930, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum, normally earned by a Major after 20 years' service, to £940 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will also be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.I), Whitehall, London, S.W.1.

The Victoria Hospital for CHILDREN, Tite Street, Chelsea, S.W.3.
(Beds 138.)

The Committee of Management invite applications for the post of SENIOR RESIDENT MEDICAL OFFICER (male), vacant February 1st. The appointment is for nine months and renewable for a further six months. Salary £250 per annum, with board, lodging, and washing.

Candidates must have previously held a Hospital appointment. They must attend the Hospital for the purpose of an interview on Friday, January 17th, at 4.30 p.m. (No travelling or other expenses will be paid.)

Applications, with copies of three recent testimonials, should be sent to the Secretary not later than first post on Wednesday, January 15th.

By Order,
D. ST. JOHN BAMFORD,
Secretary.

The Victoria Hospital for CHILDREN, Tite Street, Chelsea, S.W.3.
(Beds 138.)

The Committee of Management invite applications for the post of OUT-PATIENT ANÆSTHETIST. To attend on Monday, Wednesday, and Thursday mornings. A payment of 10/6 per attendance will be made.

Candidates must attend the Hospital for the purpose of an interview at 4.30 p.m. on Friday, January 17th. (No travelling or other expenses will be paid.)

Applications, with copies of three recent testimonials, should be sent to the Secretary not later than first post on Wednesday, January 15th.

By Order,
D. ST. JOHN BAMFORD,
Secretary.

Croydon General Hospital.

A vacancy occurs on the Honorary Staff of the above Hospital for a GYNÆCOLOGIST, and candidates for the appointment are requested to forward their applications, together with statements of their qualifications and experience, to me on or before January 25th, with copies of three testimonials.

GEORGE H. DAMS,
December 30th, 1929. Secretary.

Somerset County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER.

Candidates must possess a Diploma in Public Health and have had experience of the general administration of a Public Health Department, of School Medical Inspection work and its administration, and of Mental Deficiency work. Experience in the treatment of venereal diseases under modern methods is also necessary.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the County Medical Officer of Health and will carry out such duties as the County Council may assign to him from time to time.

The salary will be at the rate of £750 per annum, rising by annual increments of £25 to a maximum of £900.

The appointment will be made subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. Office and travelling expenses will be provided. Particulars as to the terms of the appointment, duties, qualifications, etc., may be obtained from the undersigned.

Applications, stating age, qualifications, and previous experience, together with copies of not more than three recent testimonials, to be forwarded to me not later than January 16th.

Personal canvassing will be a disqualification.

County Health Dept., Boulevard, Weston-super-Mare. W. G. SAVAGE, County Medical Officer of Health.

Administrative County of LONDON.

TEMPORARY ASSISTANT MEDICAL OFFICERS.

The LONDON COUNTY COUNCIL invites applications from registered Medical Practitioners (men and women under 45 years of age on January 20th, 1930) for inclusion in the panel for the year 1930-31 for filling vacancies for Temporary Assistant Medical Officers for School Medical work. The inclusive rate of pay is 30s. a session of 2½ hours, subject to periodical review.

Except in special circumstances married women are ineligible.

Special experience of the medical examination of children is necessary. Employment will depend upon the needs of the work, but normally practitioners will work three sessions a week during school terms.

Applications must be made on the official form, copies of which (with full particulars) may be obtained by sending a stamped addressed foolscap envelope (marked "Temporary Medical Staff") to the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1.

Forms must be returned by January 20th, 1930. Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

Metropolitan Asylums Board.

The Board invite applications for appointment as JUNIOR ASSISTANT MEDICAL OFFICER in their Mental Hospitals Service. Salary £500 per annum, rising after 3 years' approved service to £560. Candidates must be under 40 years of age and should hold, or should be prepared to undertake to read for, the Diploma in Psychological Medicine. The appointment is renewable annually and is made in the first instance to March 31st, 1931.

If the candidate appointed is required to reside in the Institution to which he is allocated, a charge fixed by the Board's Finance Committee will be made for such residential allowances as may be authorised.

Forms of application may be obtained by sending stamped addressed foolscap envelope to the Clerk to the Board, Metropolitan Asylums Board, Victoria Embankment, E.C.4, to whom they should be returned not later than January 20th.

ALLAN POWELL,
Clerk to the Board.

Papworth Village Settlement,

near CAMBRIDGE, for the Treatment of all forms of Tuberculosis. Over 300 Beds (male and female).

Applications are invited for the post of SECOND ASSISTANT MEDICAL OFFICER. Salary £350 per annum, with board, lodging, and laundry.

Applications are also invited for the post of HOUSE PHYSICIAN. Salary £100 per annum, with board, lodging, and laundry. The appointment is for six months.

Applicants for these posts must be male and single, and all applications should be sent to the Medical Director, Papworth Village Settlement, Papworth Hall, Cambridge, accompanied by copies of not more than three references.

Papworth, December 30th, 1929.

Nottinghamshire County Council

TUBERCULOSIS OFFICER.

Applications are invited for the appointment of Tuberculosis Officer at a salary of £750 per annum, with travelling expenses according to the Scale approved by the County Council.

Candidates must be fully qualified and registered Medical Practitioners, with special experience in the diagnosis and treatment of tuberculosis, and should have held resident House appointments in a General Hospital for at least six months after graduation. The possession of a Diploma in Public Health is desirable.

The person appointed will be required to take charge of County Dispensaries and to perform such other duties as may be prescribed from time to time. He will be a member of the Staff and act under the control and direction of the County Medical Officer of Health, and will be required to devote his whole time to the duties of the office and to reside in such part of the County as may be approved.

The appointment will be terminable by three months' notice on either side, and the successful candidate will be required to pass a medical examination.

Applications, on the prescribed form (which may be obtained from me), accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than January 18th.

K. TWEEDALE MEABY,
Clerk of the Nottinghamshire County Council.

City of Birmingham.

The Public Health Committee invite applications from Medical Women for the post of MEDICAL OFFICER for Maternity and Child Welfare. *Applicants must have had Children's Hospital and* Maternity Hospital experience. The Diploma of Public Health is desirable. Salary £600 per annum. The candidate appointed will be required to join the Birmingham Corporation Superannuation Scheme, and for this purpose to pass a medical examination. The appointment will be terminable by one month's notice on either side. Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, Council House, Birmingham, and returned to him on or before January 20th. Canvassing will disqualify.

City of Sheffield.

ASSISTANT TUBERCULOSIS OFFICER.

Wanted, a male (unmarried) Assistant Tuberculosis Officer, to reside at WINTER STREET HOSPITAL, and to devote his whole time to the Municipal Tuberculosis Scheme.

Salary £450 per annum, rising to £500 per annum by annual increments of £25, with board, residence, and laundry.

Applicants must be registered Medical Practitioners, with not less than three years' experience.

Applications, stating age, qualifications, and experience, with copies of testimonials, to be sent to the undersigned on or before Jan. 18th.

Town Hall, Sheffield. FRED. E. WYNNE, Medical Officer of Health.

Bloomsbury Dispensary,

12, *Bloomsbury Street, W.C.1.*

Occult Constipation

Occult constipation (from an X-Ray) 24 hours after a paste bismuth meal. There has been one small stool as usual. Note the deep haustrations and partial dilatation of the cæcum.

THE menace of occult constipation lies in the fact that the patient may have regular daily evacuations, and is therefore unaware of the constant retention of fæcal matter, which may ultimately form a hard and deep coating on the intestinal wall, leaving but a small passage through which painful and partial evacuation takes place.

When headaches, lassitude, and the conditions usually associated with the development of intestinal toxæmia lead to the suspicion of hidden constipation, the reliance of many physicians is on AGAROL Brand Compound, *the original mineral oil and agar-agar emulsion.* Combining lubrication with softening of the fæcal mass and gentle peristaltic stimulation, AGAROL Brand Compound is particularly indicated in cases of occult constipation — because of its positive, yet gentle action, without habit formation.

AGAROL Brand Compound is the *original* Mineral Oil–Agar-Agar Emulsion and has these special advantages:

Perfectly homogenized and *stable*: *pleasant taste* without artificial flavouring, freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage; no griping or pain, no nausea or gastric disturbances; not habit forming.

THE RIVIERA

The PARK LANE PRIVATE HOSPITAL and CONVALESCENT HOSTEL

LA CALIFORNIE, CANNES, A.M. FRANCE

This Hospital has been recently opened and can accommodate patients either in small single rooms or in suites, consisting of bedroom, sitting room, bathroom, and sun room. All rooms have uninterrupted views over the Mediterranean, as the situation of the Hospital is very high and has a southern aspect.

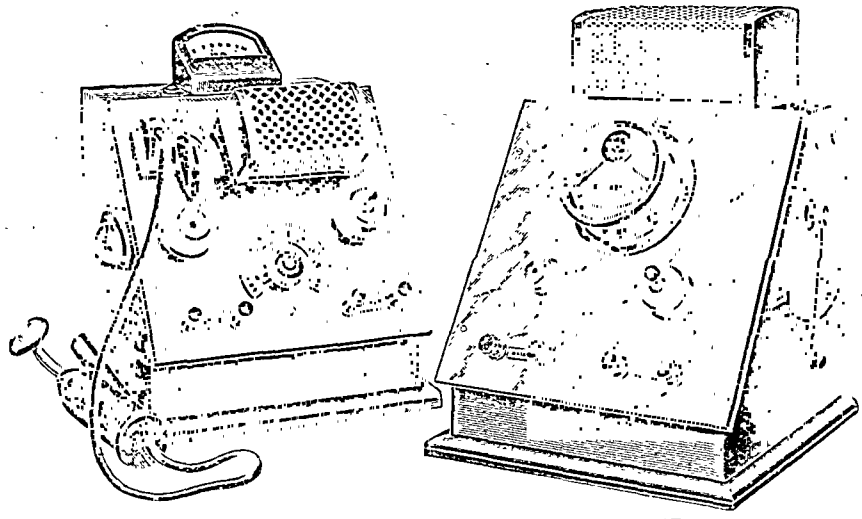
There is a perfectly equipped Operating Theatre, also Laboratory, X-ray, and complete Electro-therapeutical Departments.

Only English-trained Nurses throughout the Staff.

Lifts (both passenger and service), telephones, etc., installed.

A separate villa has been arranged for the reception of convalescent patients, with Vita-glass windows and wide balconies. Also a tennis court for their use in the extensive grounds.

All particulars concerning fees, accommodation, etc., can be obtained from the Matron, Miss M. ADAM (late Matron, Queen Victoria Memorial Hospital, Nice).



Telephones: CANNES 1452 & 2822. Telegrams: "PARKLANE, CANNES."

THE HOSPITAL IS OPEN ALL THE YEAR.

DIATHERMY APPARATUS

FOR THE GENERAL PRACTITIONER

THE EXTRA PHARMACOPŒIA

By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition.

Vol. I, 27/6 net; postage 6d.
Vol. II, 22/6 net; postage 4d.
Complete Work (2 Volumes) 50/- net, post free.

In Two Volumes.

Vol. I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.
Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: "*Has a well-established reputation as a most useful and convenient work of reference.*"
LANCET, Nov. 2nd, 1929, says: "*A clear and authoritative publication of the highest value.*"

An up-to-date Book for everything on the *Therapeutic Use of Drugs*. *It embodies the Latest and Most Varied Information* on Chemistry, Pharmacy, Therapy, and numerous other subjects

LONDON: H. K. LEWIS & CO. LTD., 136, Gower Street, W.C.1

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.
Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"*It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide.*"—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

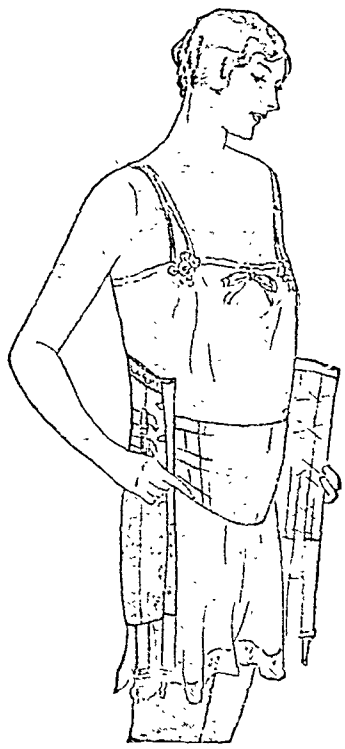
When Operation for Hernia is Inadvisable—

A Spencer Abdominal Belt or Supporting Corset gives Excellent Results.



TO be effective a support for hernia must stay in place. Each Spencer support is designed especially to meet the needs of the individual who will wear it. This assures perfect fit and adjustment at all times, since the Spencer support for hernia is non-elastic as well as individually designed.

Spencer hernia supports are comfortable. They fit, and they have no hard rubber or heavy metal parts.

They are also strong and well made, in order to provide both durability and absolute security for the patient.

Spencer supports for reducible umbilical hernia may be prescribed with or without auxiliary pads, according to the patient's need.

For cases of non-reducible umbilical hernia, a special protecting pad used with a Spencer Belt will shield a small hernia of this type from injury, and will prevent increase in the size of the hernia mass. For a very large non-reducible umbilical hernia, the Spencer Belt is made so that the mass is gently but firmly supported, to provide comfort and to guard against increase in the size of the hernia. Inguinal hernia, ventral hernia at the site of an operation scar, can be properly taken care of by a Spencer support.

SPENCER
SUPPORTING CORSET
Front unclasped and held back to show the inner supporting section.

The Spencer Corsetière will call at your surgery or at your patient's home to take measurements under your supervision.

We issue the following booklets on the use of Spencer Supports: Hernia, Sacro-iliac Strain, Enteroptosis and Intestinal Stasis, Movable Kidney, Pregnancy and Post-partum Support. We will gladly send you any of them in which you are interested.

We take this opportunity of thanking our numerous professional clients for their friendly assistance during the past year.

Light therapy demands that increasing attention of the medical profession which, in the words of a prominent authority, "will materially assist to stem the charlatanry which flourishes on professional neglect."

Hanovia Quartz Lamps, manufactured in England by specialists in apparatus for light therapy, are unapproached in value, performance, and appearance.

Our twenty-four years' intimate relation with the medical profession assure you of information stated in ethical form. We distribute no publicity matter which does not bear the confirmation of contemporary medical opinion.

May we send you literature Set No. 9?

"HOMMEL'S HAEMATOGEN"

A natural organic TONIC associated with nourishing albuminous proteids.

AN EFFICACIOUS REMEDY IN ALL FORMS OF ANÆMIA, associated with constitutional diseases.

Obtainable in Syrup *and* Tablets.

"SEDIN"

Nervinum-Sedativum

Consisting of

Pot. Brom.	0.4	gramme	(grains 6½ approx.)
Sod. ,,	0.4	,,	(grains 6½ approx.)
Ammon. ,,	0.2	,,	(grains 3 approx.)
Salt	0.1	,,	

combined with Vegetable Extract in form of soup tablets. (A disguised dietetic form.)

Samples free and carriage paid on application to—

HOMMEL'S HÆMATOGEN & DRUG CO., 121, Norwood Road, Herne Hill, London, S.E.2

Irritable Bowel

Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

Local Anæsthesia in Surgical Practice

TUMOUR OF BRAIN.

TYPICAL CASE.

L. B., male.

Diagnosis: Brain tumour in the left arm and leg centre.

Operation: Decompression. Ligation of varicosities.

Anæsthesia: 100 c.c. of a 1 per cent. Novocain-Adrenaline solution.

Operation: Ten minutes after making the infiltration a horseshoe-shaped flap was turned down on the right side of the vault of the cranium. The skull was opened by means of the Martell drill and a bone flap was turned down by the use of a motor saw and a dura guard. This procedure was entirely painless to the patient, and he did not even complain of the grating of the saw. The patient made a prompt recovery. —Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify " Novocain " for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

The Urinary Antiseptic for Oral Use

In the treatment of cystitis, pyelitis, prostatitis, urethritis, and other diseases of the urinary system, the outstanding properties of

CAPROKOL

have proved to be of remarkable value.

Caprokol is at once a powerful bactericide and a valuable analgesic.

The first result of Caprokol treatment is the soothing effect produced upon the mucosa of the urinary tract—pain ceases, fever subsides, and the patient enjoys restful sleep uninterrupted by frequent micturition; persistent treatment results, in almost every instance, in complete sterilisation of the urinary tract.

OVALTINE

MALNUTRITION IN CHILDREN

Nervous and mentally unstable children are numerous, and their condition, being naturally deep rooted and inherent in the organism (as neuroses and psychoses are not of sudden onset), is difficult to remove.

From its composition and properties physicians recognize that "Ovaltine" is especially well adapted to the feeding of growing children, both in health and sickness. The mere fact that when added to a vitamin-free diet it will almost at once set up in a puny, poorly grown, and malnourished animal a growth and development normal in every respect, should in itself carry conviction.

When, however, the results of our laboratory experiments are amply and widely confirmed by the successful use of "Ovaltine" in clinics, and by prominent pediatrists throughout the world, assuredly it may be said that assurance has become doubly sure. The delicious flavour of "Ovaltine" appeals particularly to children, and they thrive upon this perfectly balanced food in a completely satisfactory way. A pamphlet, well illustrated and dealing at length with the scientific tests referred to above, will be gladly posted on request.

A liberal supply for clinical trial sent free on request.

ERYTHEMA PERNIO

(Chilblains)

THE examination of tissue under the microscope in cases of Erythema Pernio provides ample confirmation of the widely held opinion that the origin and development of the condition is due to imperfect structure, or increased permeability, of the walls of the superficial blood-vessels. The exposure of the extremities to cold certainly aids the infiltration of the tissues, but the true underlying cause can best be described as a defective innervation or physiological condition of the vessel walls.

Calcium-sodium-lactate (Wulfing) i.e., Kalzana, is successful in the treatment of Erythema Pernio because, in its manufacture, the principles upon which calcium retention depends receive first consideration. The most important factor in the establishment and maintenance of blood alkalinity in man is the oxidization of the alkaline salts of organic acids, and this is definitely influenced by the sodium lactate element of Kalzana. Consequently the blood is able to retain the calcium constituent and use it for the relief of chilblains, or any other morbid manifestation of calcium deficiency.

Kalzana has been very successful in three cases of patients suffering from severe chilblains. I began the treatment at the end of October, and my patients were particularly free from them through the winter. ——M.R.C.S., F.R.C.P.

Dispensed by Chemists in air-tight packets containing 50 and 100 plain tablets.

"THE TREND OF PHARMACOLOGY."

"The modern trend of pharmacology is in the direction of what we call chemotherapy, which, whatever it meant in the beginning, now means specific therapy—that is, the production of a chemical substance which, when administered to a diseased patient, destroys the causal agent of disease directly or indirectly without injuring the patient."

Prof. W. E. DIXON, M.D., F.R.S.,
Examiner in Pharmacology, Universities of Oxford and Cambridge.

Dimol, the non-toxic intestinal bactericide, has for over nine years been recognised as such a chemical substance.

"By the introduction of dimethylomethoxyphenol (Dimol) the putrefactive organisms are destroyed and the Bacillus coli, owing to their greater powers of resistance under the changed environment, are enabled to cast off their pathogenic virulence and resume their normal character.

"The significance of this addition to our therapeutic resources suggests the beginning of a new era in the treatment of disease; the fact that the poison trap of the intestines can now be brought under control may prove to be the solution of many hitherto undetermined pathological problems."

The New York Medical Journal & Medical Record.

Samples and Literature will be sent on application to the
DIMOL LABORATORIES, 40, Ludgate Hill, London, E.C.4.

Sample on request

ÆTHER PURISS.
B.D.H.

The knowledge that the brand of ether which is sent to the operating theatre is the purest obtainable creates a feeling of quiet confidence in the mind of the anæsthetist and of the surgeon.

The administration of Aether Puriss. B.D.H. ensures comfortable anæsthesia without risk of after-effects of toxic origin. Aether Puriss. B.D.H. contains no trace of peroxide, aldehyde or other products which cause undesirable post-operative effects.

Descriptive literature giving particulars of the stringent standard of purity to which Aether Puriss. B.D.H. conforms will be sent on application.

HOW GIBBS HELPS THE DOCTOR

Gibbs teaches the Golden Rule

PREVENTION IS BETTER THAN CURE

Prevention of decay is the keynote of all Gibbs advertising and propaganda. Gibbs try to teach the Public to regard the loss of even one tooth as a tragedy of the first magnitude.

By the constant reiteration of a few simple, wholesome precepts, Gibbs endeavour to impress strongly upon the Public the vital necessity for absolute cleanness of the mouth as a first principle in preserving the teeth. Following that, any authoritative utterances by Doctors or Dentists upon any phase of teeth preservation, are given the widest possible publicity by Gibbs.

The House of Gibbs welcome, at all times, suggestions from Doctors or Dentists as to any special phase of dental prophylaxis which, in the Doctor's or Dentist's opinion, should be specially emphasised at any particular time or in any particular locality.

Gibbs constantly remind the Public that a little care and thoughtfulness in matters of dental hygiene is repaid a thousandfold in returns of beauty, health, happiness and business and social success.

The Doctor and Dentist are always presented as the Highest Authorities upon all matters connected with the teeth. Very largely as a result of Gibbs propaganda, there is an increasing acceptance upon the part of the Public, of any and all advice or instruction given by the Medical Profession.

Thus, in so far as they are able, Gibbs are working hand in hand with the Doctor and Dentist, looking forward to that day when the greater part of all dental work will be purely preventive.

GIBBS DENTURE TABLET

Gibbs new Denture Tablet is for cleaning Dental Plates, Bridgework (both gold and vulcanite) and artificial teeth. It gives a high polish, removes stains, makes plate or teeth sterile and antiseptic without in anyway injuring the softest gold or the finest vulcanite or platinum. The formula has been submitted to and approved by important members of the Medical Profession.

Literature, propaganda material, kinematograph films, leaflets, etc., as well as samples, are always freely at your disposal. Address: Dental Dept. 200wx, D. & W. Gibbs Ltd., London, E.1.

GD/Dr/1a

Action of Antiseptics on Organic Salts

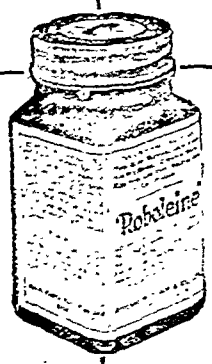
Important Findings

The left hand test tube below shows Lysolat in a state of perfect emulsification in a 3% solution of Sodium Chloride, whilst a well-known liquid Lysol (right hand test tube) has broken down under the same conditions.

One of the problems of antiseptic practice has been the rapid deterioration of emulsified disinfectants on contact with organic matter. As doctors know only too well, the salts break up the emulsion, throw out the active principle of the antiseptic, and destroy its bactericidal value.

Experiments with 10% solutions of many lysols and other disinfectants in wide use have revealed that Lysolat alone preserves a perfect emulsion in salt solutions and in sea water; in fact, a solution of 3% sodium chloride, or for that matter any chloride, would destroy any other cresylic acid preparation, whether proprietary or otherwise.

Surgeons will realise the significance of these tests, for obviously the physical action of the antiseptic in disintegrating dirt, grease, and blood clots, and attacking the bacteria within, remains unimpaired. Lysolat is specially sensitised with a protective colloid, which preserves its efficacy under the most difficult conditions encountered by the surgeon or the chemist.



Lysolats

PATENT 118667 (LYSOL TABLETS)

Lysolats are packed in handy tins containing 40 and 80 tablets (at 1/3 and 2/- respectively), and also in tins of 1,000 tablets.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney St., London, S.E.1

Roboleine

The Food that Builds the Body.

FOR NEARLY A CENTURY
THESE ESSENCES
HAVE BEEN PREFERRED
BY THE MEDICAL PROFESSION

JUST on a hundred years ago Brand & Co. first offered their Meat Essences. From that time until now Brand's Essences have achieved fame because of the exclusive conditions and care under which they are manufactured.

Experiments have proved that Brand's Meat Essences are powerful exciters of the gastric juices. They rouse appetite, and their goodness is rapidly absorbed without strain on the digestive organs.

Brand's Essences are the pure juices of the finest freshly killed chickens, beef and mutton extracted by an exclusive process under hygienic conditions. No preservatives or other substances are added. Brand's Essences (Beef, Chicken and Mutton) are obtainable at chemists and stores throughout the world in small and large-sized tins and jars. Brand & Co. Ltd., Mayfair Works, Vauxhall, London, S.W.8.

BRAND'S ESSENCES

PERNAEMON
LIVER EXTRACT

Prepared according to the American Process

A highly effective treatment for Pernicious and various forms of Anæmia

Each vial represents 100 grammes (4 ozs. approx.) of fresh liver. A reliable preparation at a REASONABLE price.

Manufactured by The ORGANON LABORATORIES, OSS (Holland).

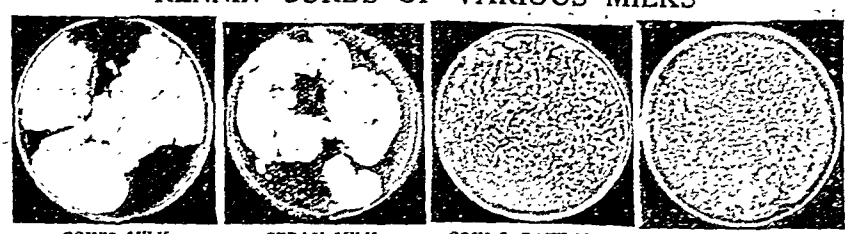
DIGESTIBILITY

In contradistinction to the heavy, large, and indigestible curds which are given by the action of rennin on Cow's milk and milks dried by the spray process, reconstituted Cow and Gate Milk gives a light flocculent precipitate, very similar to that of Breast Milk. A recent investigation has shown that the same results are obtained by using enzymes from human sources and that the improved Cow and Gate Roller Process does not alter the proteins to an extent which interferes with their subsequent easy digestion.



The use of such alkaline agents as Sodium Citrate and Lime, to prevent this leathery curd formation, is therefore entirely superseded. In fact, it has been shown (Hess: Feeding and Nutritional Disorders in Infancy) that these agents, while retarding the formation of hard curds, also inhibit, most decidedly, peptic digestion owing to their increased buffer action, and in addition they have a destructive effect on Vitamin C.

Cow & Gate Milk Food

"Cow's Milk made safe and suitable for Baby."

This denaturisation of the proteins in Cow and Gate is brought about by an improved Roller Process, which also preserves intact the Vitamin and mineral content of the original rich milk of Somerset and Dorset.

RENNIN CURDS OF VARIOUS MILKS

COW'S MILK | SPRAY MILK | COW & GATE MILK | BREAST MILK

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

R AND C

Produces normal functioning of the entire glandular system

COMPOSITION. Protonuclein is the pioneer organo-therapeutic product, and the popularity it enjoys to-day, a quarter of a century after its introduction to the medical profession, speaks eloquently for the sound reasoning that was responsible for its inception. Protonuclein is a true pluri-glandular product, consisting of a physiological association of those glandular structures particularly rich in nuclear material, namely the Thyroid, Thymus, Spleen, Pancreas, Stomach, Salivary, Lymphatics and Brain (including the Pineal and Pituitary).

INDICATIONS. Protonuclein restores, regulates and augments the activity of glands or organs of the internal secretory system that may be apathetic, deficient or deranged.

FORMS. Protonuclein is issued to the Medical profession in tablets. Bottles of 100, 500 and 1000. Stocked by all first-class Pharmacists.

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

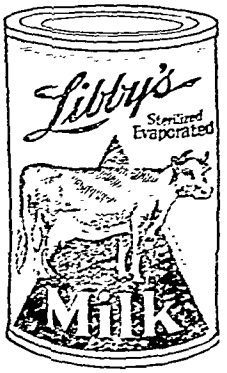
A Lovely, Healthy, Active Boy-

because he is rightly fed –

He's contented, too—a happy, growing boy. Activity is the sign of baby happiness, and babies fed on Libby's Milk are active and contented.

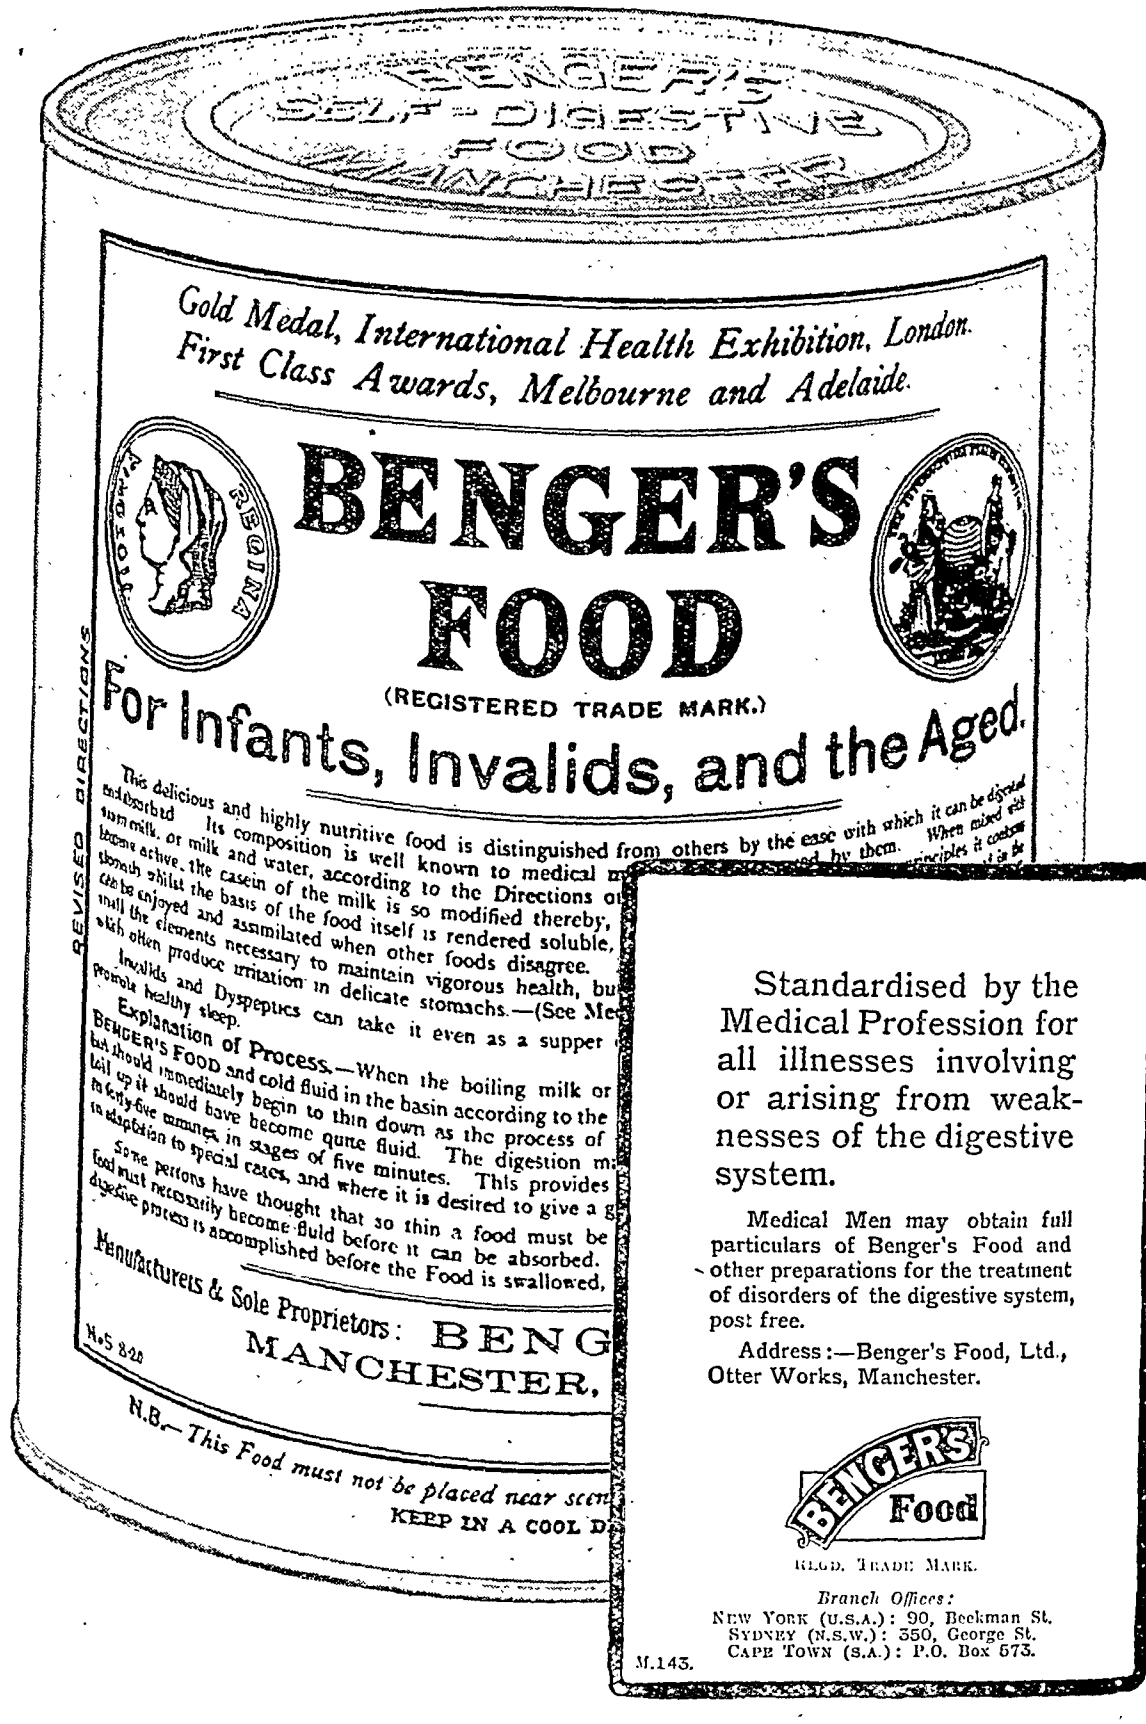


There are sound scientific reasons for these statements. Libby's Milk is protected from all contamination. It is also "homogenized" and sterilized, the modern, scientific method of making certain that Libby's Milk shall not only be absolutely pure, but always in such a condition that the most delicate of infants can immediately assimilate it for healthy growth and happiness.

Libby's Milk is uniform in consistency and quality. Perfectly pure, germ-free, with all the solids and fats in perfect suspension. Wherever a Baby is put on Libby's Milk there is general surprise at its progress, better health, and contentment.

Libby's

Evaporated Milk



£1,000 will be paid to any Hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.

(*Aesculapius*)

LIVER THERAPY

Studies on the combination of liver and iron indicate that while neither is always satisfactory, the two combined have proved effective. For the treatment of the severe secondary anæmias the use of liver in itself is of inconstant value. Likewise the administration of iron, while undoubtedly beneficial, does not always ensure that degree of improvement which is desirable.

HEPATEX WITH IRON

provides a rational treatment for Severe Secondary Anæmias.

Also the addition of iron enhances the value of Hepatex in Pernicious Anæmia.

A special form of iron has been evolved in our Laboratories which, compared with standard iron preparations, is greatly superior as regards assimilation and absence of gastro-intestinal disturbance. Combined with HEPATEX, our highly concentrated Extract of Liver, a most stable and palatable preparation is produced.

A one drachm dose contains one grain of metallic iron and the essential therapeutic principles of two ounces of fresh liver. One or two teaspoonfuls per day will in most cases be found ample.

In 2 oz. bottles ... ... **7/6** *each.*

GLANOID

40% SPLEEN
SOLUTION
IN THE TREATMENT OF
ECZEMA & URTICARIA

Dr. Thos. M. Paul, in "The Urologic and Cutaneous Review," Vol. XXXIII, No. 11, 1929, states in the opening paragraph:—

"To state that hives will disappear in fifteen minutes, that the itching and oozing of an eczema will cease in half an hour, and that an eczematous lesion, regardless of its degree of lichenification, will vanish in a few days, as the result of a hypodermic injection, seems preposterous, yet such has been the writer's experience in a series of sixty-one cases."

We have a few copies of the actual article for loan to interested Dermatologists.

STONE OBJECT OF UNCERTAIN USE, INSCRIBED WITH WORDS IN THE WRITTEN CHARACTERS EMPLOYED BY THE MINÆANS WHO HELPED TO CIVILISE ARABIA AND BUILT UP ONE OF ITS EARLIEST KINGDOMS.—Many inscriptions and traces of settlements left by the Minæans provide evidence of a vigorous kingdom existing side by side with that of the Sabæans, and, according to some scholars, of even earlier beginning. The native territory of the Minæans cut into that of the Sabæans, a circumstance which entailed frequent struggles between the two. Their capital, Ma'in, lay north of Ma'rib. The names of about thirty kings of Ma'in are known from native monuments. A most important Minæan colony existed at el-Ula in North Arabia, on the caravan route to Gaza; this was a centre of civilisation during a very long period. Their business enterprises seem to have led them far, for the epitaph of a Minæan agent in the incense traffic has been found upon a sarcophagus in Egypt, while an altar to Wadd, one of their most honoured gods, was set up in Delos. The object here reproduced—perhaps an amulet or a weight—bears the words "Wadd is a father." Wadd, who appears to have been the god of friendship, is usually qualified by a word the root of which means "to help."

The Savill Memorial Oration

ON

LOCALIZATION OF FUNCTION IN THE NERVOUS SYSTEM.

DELIVERED AT THE ROYAL COLLEGE OF PHYSICIANS ON DECEMBER 2ND, 1929,

BY

JAMES COLLIER, M.D., F.R.C.P.,
CONSULTING PHYSICIAN AND EMERITUS LECTURER ON NEUROLOGY, ST. GEORGE'S HOSPITAL.

I HAVE chosen the subject of localization of function in the nervous system because I have thought for some years that the information obtainable by our students from the current textbooks of medicine and of neurology is very much behind the times, when compared with the results of modern biological and physiological research, and that this information does not convey a satisfactory working hypothesis to the medical man. The subject is, moreover, very much in the air at this moment, for in the few months since I accepted this oration and decided upon this subject two exhaustive reviews have appeared, the one in America by Marion Hines, and the other in France by R. Brugia, under a preface by Pierre Marie. In comparison with these detailed and lengthy works, anything that I can put before you in the short space of an hour must be but a brief outline of present opinion, supported and modified perhaps a little by my personal clinical observations. There was another excellent review upon "cortical localization" thirteen years ago, from the physiological and experimental aspects, by the distinguished physiologist Professor Graham Brown.

I may well introduce my subject by putting before you a quotation from the conclusions from each of these reviews, beginning with that of Professor Graham Brown, who wrote:

> "The experimental evidence gives no grounds for the supposition of the localization of the function of voluntary movement in the 'motor area' as distinguished from any other part of the cortex."

Graham Brown sought to find proof that the "motor area" was more than a mere spot upon the outgoing path for voluntary movement, and by his experiments showing "primary facilitation," in which careful unipolar stimulation of a cortical point in the "motor area" raised the excitability of that cortical point, and those showing "secondary facilitation," in which similar stimulation of the same area caused the neighbouring region of the inexcitable post-central cortex to become excitable, he claimed to advance a proof that the "motor area" was something little more than a mere receiver and transmitter upon chief outgoing path for voluntary movements, and that nge and modification can take place at this station.

Dr. Marion Hines, who writes rather as a reviewer than a pioneer upon this subject, concludes in the following s:

> The diagrams of local representation of function in the cerebral cortex so prevalent in the last part of the nineteenth century e gradually become dimmer until finally point localization has peared even from the motor cortex under the careful experimental analyses of Leyton, Sherrington, and Graham Brown. the projection of the retina upon the calcarine now remains. yet in the light of our present knowledge to consider the al cortex as equipotential is hardly justified, nor to hold pinion that the kind is immaterial, providing the bulk icient."

Hines might, with a little thought, have rid her of the calcarine cortex, for the succinct projection of tina upon the calcarine is admittedly a precise ing of the impingement of visual afferents upon the The calcarine cortex is an important station upon path by which visual impressions reach the cortex n, at any rate, and holds a similar position with to the visual path as does the motor cortex to the tgoing path, in that lesions of these two regions ese paths respectively. Dr. Hines has rejected a localization of function of former days for a much more vague, indefinite conception of localization of function. You may remember that this was also the position taken by Sir Henry Head in his later writings. But this conception of vague localization has one thing in common with the old conception of succinct localization, and that is that both are centred around the regions where great incoming paths impinge, and where great outgoing paths emerge from the cortex, interference with which is readily manifest in disturbance of function, and that blocking of such paths cannot be excluded as causing a large part of the functional loss resulting from ablation of these regions. I do not wish to infer that the conception of vague localization of function is wrong or untenable, but it requires careful criticism. Surely it is impossible to think otherwise than that a part of the cortex—the latest and highest development in evolution—which receives the visual impressions will be especially important in connexion with the visual function otherwise than as a receiving and transmitting station, and similarly in the case of the motor emergent and other sensory receptive regions. But such thought does not altogether entail a conception of local function.

Dr. Brugia will have nothing of localization of function in the nervous system. He refers to this conception as the "seduction of all seductions," to which so many have gone under. At the end of his book of nearly two hundred pages he claims to have put forward adequate and convincing proofs that in the nervous system there are no centres of local function, neither for the reception of impressions, nor for exteriorization, nor for co-ordination, nor for volition. He commences by pointing out that the nerve cell is a structure appended as it were to the out-side of the true fibrillar conducting nerve substance which passes through it to end elsewhere, and that the proved function of the nerve cell is only nutritional, and that it cannot be a centre of function. He refers to the primary metameric nerve unit, and says with truth that from the peripheral receptor, through the afferent and nerve cells, to the efferent and the muscle, no part can be called the centre of reflex activity; no part can be deemed dominant over the others; every part is equally important in the occurrence of the reflex action. Reflex activity is the function of the metameric nervous unit as a whole. Brugia builds up the nervous system physiologically, as it is built up morphologically by interconnexion and fusion between the primary metameric units, and when this interconnexion begins there is convergence of paths and modification of the result of activity in any one segment—there is co-ordination. This is, of course, Sherrington's "principle of convergence." The forward metameres become highly developed and dominant from specialization, and the brain appears. But the whole nervous system acts as did the primary metameric nervous unit, not in terms of separate function in its several parts, but as a whole and entirely reflexly. He calls the metameric units "neuromyomes." Though he denounces a little loudly the earlier pioneers upon this subject, his summary is worthy of consideration, and especially does it bring into prominence the great importance of bearing clearly in mind the high part played by the peripheral nervous system, both receptors and effectors, in the activity of the higher parts of the nervous system, and the profound derangement of function which accompanies the severance of communication between these parts.

In my quotations from these three reviewers I have said enough to prove that a change of thought has been taking place with regard to the nature of activity of the various parts of the nervous system, and I must proceed to give very briefly some of the reasons for this change. I will first refer to the cerebral cortex.

The cerebral cortex, described by Sherrington as the principal ganglion of the distance receptors—namely, the receptors of smell, sound, and visual impressions—was in the earlier stages of its development the principal ganglion of the receptors of smell only, and its connexions with the functions of sight and hearing are secondary connexions. It is developed as an appendage to the olfactory paths, the primary connexion of which was with the thalamus. It begins as an outgrowth between the two primary masses of grey matter in which the olfactory tract terminates on either side, the inner of these remaining as

the hippocampal region and the outer as the pyriform lobe or uncinate region, and develops into the dominant part of the nervous system, perhaps because of the immense importance of the function of smell in finding food and in scenting danger. In some animals whose activity depends very largely upon the sense of smell, the severance of the olfactory tracts causes a complete destruction of the function of the brain. A shark, for example, with the olfactory tracts cut resembles in every way a shark with its forebrain removed. It is apathetic, motionless, and it will not feed. Appetite and activity are lost. I will now compare the shark with another fish, which does not rely entirely upon smell, but chiefly upon sight in getting its food and avoiding its enemies. If we remove from this second fish the forebrain, which is not much connected with visual function, it does not make great difference to him. He remains lively, he feeds well, and will select his food and distinguish between red worms and white worms. If we blind him we shall reduce him almost to the level of the decerebrate shark. I am stressing this point to impress you with the very great reduction of function which occurs in the higher regions of the nervous system from de-afferentation, whether this deprival of afferents occurs in the peripheral nervous system or, and this is even more important to my subject, in the central nervous system—for example, in the immediate subcortex. I may here repeat the story of the decerebrate frog and the flies, which has been often quoted as suggesting how much the forebrain adds to the capacity of the nervous system of this lowly animal. Such a frog does not compete well in the struggle for existence when in a comfortable aquarium with other frogs. But if we take this frog without forebrain and place him with a normal frog in a covered glass bowl and set free a dozen flies within that bowl, the decerebrate frog will get all the flies and the normal frog will get none. The reason for this is that the normal frog is aware that his surroundings are unusual and is uncomfortable; he spends his time in fear and attempts to escape, and before he has got over his embarrassment the decerebrate frog, who is not so aware and not so discomforted, but attends only to the grosser matters of appetite, has caught all the flies.

It is remarkable that the olfactory function, with which the development of the cerebral hemispheres is so intimately connected, seems not to be interfered with by any local lesion of the convolutions, whether unilateral or bilateral, provided the olfactory tracts are intact. Chatelin examined 5,000 cases of wounds of the brain, unilateral and bilateral, and found no loss of the sense of smell or taste. Our only knowledge of the connexion of these functions with any individual part of the brain rests upon the developmental and anatomical facts, and upon the occurrence of hallucinations of taste and smell in the epilepsy which may result from tumours in the uncinate region. Possibly the afferent paths of smell and taste have a very general impingement, as opposed to a local impingement, upon the cortex, and in great measure escape in local lesions of the convolutions. There are two clinical facts which seem to support the proposition. The one is that only in epilepsy commencing with an olfactory or gustatory aura does one meet with a highly organized hallucination comparable to an experience of actual life, and this hallucination may be one of hearing, of vision, of idea, or a combination of these. All other hallucinations in epilepsy and with local lesions of the hemisphere in other regions than the uncinate gyrus are crude sensations and not comparable with those of common experience. The other fact is the well-known high potentiality of a sensation of smell to rouse cerebral activity to a high pitch in the form of vivid memory. ...h high hallucinations and such sudden arousing of ...mory are compatible with the direct association ...ory path with many regions of the cortex and ...f the neopallium as part of the olfactory ...or area" of the cortex, the discovery ...tability of which by Hitzig and ...d the old theory of the phreno- ... by the clinical observations of Broca and Hughlings Jackson, seemed to place the hypothesis of local function in the several regions of the cortex upon a sound basis, has been the region in which recent experimental research has first and most disproved the tenability of this hypothesis, in its highly developed form certainly, and perhaps in any form at all. It must be borne in mind that there are three regions in each hemisphere from which movements can be elicited by unipolar electrical stimulation. One is at the posterior pole of the hemisphere and another is on the outer surface of the prefrontal lobe, both of these giving movements of head and eyes to the opposite side. The third comprises the whole of the ascending frontal gyrus, and from it, and it alone, the cortico-spinal tract or pyramidal tract arises. This ascending frontal convolution is mapped out in cortical points set in ladder-like fashion, stimulation of which produces movements of lower extremities, trunk, upper extremities, and face region from above downwards. Physiologists do not believe that the other regions of the cortex are not excitable, but that they are so much more lowly excitable as only to be aroused by such strengths of electrical stimulation as at once spread widely to other regions and render analysis impossible. One of these regions—the post-central gyrus—can be raised into a motor area by Graham Brown's method of secondary facilitation to which I have already referred.

Now in a chimpanzee Sherrington and Leyton removed the whole of the cortex from both ascending frontal gyri in two stages, separated by a considerable interval of time—the right first and the left subsequently. After each of these operations there was a temporary paralysis of the opposite side, which recovered perfectly. The left post-central cortex was then removed, but this produced no further disability. Later they examined this animal and found that no movements of face, body, or limbs could be elicited by stimulation of any part of the cortex, so that no other part of the cortex had taken on the role of electrical excitability of the removed cortex. The experimenters had removed the "cortical centres for movement," and had shown that no excitable area was left, and that none had been redeveloped. They had utterly destroyed the pyramidal system, for this had degenerated throughout. They had destroyed the post-central cortex on one side and had excluded the possibility of that potentially excitable region having taken over the motor function. They had left the chimpanzee with enough of his nervous system to recover and get along quite ably.

Now the interpretations which may be made of this sequence of events are, first, that we may believe that the cortical centres for movement were really ablated, but that the function of movement reverted to an ancestral home in the lower regions of the nervous system. This explanation, as Graham Brown points out, is possible, but most highly improbable. Secondly, we may think that the function of voluntary movement is concerned with the cerebral cortex in general, and that the ascending frontal convolution and its pyramidal tract are the chief, but not the only, outgoing path for movement, and that the ablations caused the temporary paralysis (1) because the usual way out was blocked and the alternative path took time to acquire function; (2) because the mechanism of motility was maimed as a whole by the loss of one of its elements and transcortical connexions, and time was required for compensation; (3) because some of the cortex which must be concerned especially with the receipt of impressions arousing motor activity was lost. The latter explanation is the highly probable one.

Graham Brown subsequently performed a very similar experiment, again upon a chimpanzee. He removed the whole of the cortex of the post-central gyrus, first upon the one side and subsequently upon the other. Clinical lesions of the post-central gyrus in man of this magnitude would have produced the most profound disability of the limbs and ataxy on both sides from loss of sense of position and astereognosis, for in man this post-central region has been held to be the centre for the more discriminating functions of sensibility. But this chimpanzee did not show any signs of disability at all, for within a few days of the completion of these ablations he learned to get open the cupboard in which his food was kept. [illegible]

cupboard was locked and latched and the door was tight-fitting, so that this monkey had to turn the key with one hand and the handle with the other, and had at the same time to put his foot against the impost and pull the door open. Watchful lest his crime should be detected, he even learned to do this complicated act with his back to the door—that is, without the guidance of his sight. He seemed not to have lost any of his function of sensibility at all. Graham Brown thereafter removed the left motor area of this animal, and the usual temporary hemiplegia ensued. But before a fortnight had elapsed, after repeated efforts to get the cupboard open meanwhile, he succeeded in doing so, and soon acquired his customary facility.

In considering the bearing of this experiment we must keep carefully in mind that the function of movement and the function of sensibility are not two separate functions, but that they are so intricately blended as to be inseparable. We have no consciousness of movement in ourselves except from the sensations which result in its accomplishment. We learn every skilled act by gradually laying down, by repetition, the pattern of the sensations which are produced by its correct performance. We reproduce them from the memory of these sensory patterns. We become clumsy with our skilled acts when out of practice because the memory of the finer details of the sensory pattern tends to fade, and we reinforce these again by further repetition. It was for these reasons that Bastian rejected the idea of a motor centre in the cortex, and insisted that it must be a sensorimotor centre.

In Graham Brown's chimpanzee it is certain that the post-central cortex was not the chief, nor apparently even an important, higher sensory centre, for its removal produced no disability. It was not a region in which this animal stored his memories of spatial relations and highly skilled movements, for he developed these subsequent to its complete removal; and, adding the left motor area to the extensive regions of the cortex which the animal had already lost, there was sufficient cortex left for the recovery of good function. This experiment supports further the argument that the cerebral cortex, with its afferents, efferents, and transcortical connexions, acts as a whole.

There is one other experimental fact which has a profound significance and to which I would especially draw your attention. The "motor area" for the face, jaw, tongue, and larynx, to which I may refer as the face-excitable cortex, is well marked in all animals from marsupials upwards, and it is a large area in the higher animals. Ablation of this face-excitable cortex, either unilateral or bilateral, has never produced even the least transitory paralysis of face, jaw, tongue, or larynx. Sherrington removed the whole of the face-excitable cortex in a young chimpanzee, with the result that the animal became at once more grimacing, more teeth-chattering, and much more noisy than before. One must conclude, therefore, for these animals that there is no localized centre of motor function for these important regions in the cortex, but yet that there is always an excitable path to these regions emerging locally from the cortex which does not seem to be the usual or even the important path of emergence for movements of face, jaw, tongue, and larynx, since complete ablation produces no disturbance of function.

When one compares the results of these experiments of cortical ablation in so high an animal as the chimpanzee with the results of pathological lesions of the same regions in man (which usually, but not invariably, obtain), there is difficulty in correlating the two. While it is allowable to use comparison between a lower and a higher animal in general, it is particularly unsafe to do so in connexion with the nervous system of man, the function of which is so far removed above that of the highest animal, and in which so much of the structural as well as functional development occurs after birth and during the course of training; and individualities of structure are without doubt sometimes determined by that training, so that the brains of men are not all fashioned alike, and may not behave alike when troubled with local injury. The chief difference between the brain of the chimpanzee and the brain of man is striking—not that the latter has more grey matter, but that he has much more white matter, weight for weight. The supremacy of the brain of man is associated structurally with a much richer association and more direct connexion between its several parts, and is therefore a better organ functionally; on the other hand, it seems to have became more dependent upon solitary afferent and efferent paths than is the case in lower animals, and therefore its function is more disturbed by local lesions. From birth to adult age this dependence upon solitary paths seems to increase.

Clinically one does not meet with lesions comparable to the accurate cortical removals of experimental physiologists. There is one case commonly cited in which Horsley removed the arm-excitable cortex of a boy on the right side. This patient is said to have recovered sufficiently to play tennis, though never so well as before the operation, and so may be said to show to some degree the recovery which occurs in apes. Pathological lesions are rarely confined to the cortex, and when there is evidence that a lesion is chiefly one of the cortex and not progressive, recovery of function occurs which may be complete, as in the experiments on animals, if the lesion is of the motor area, but little or no recovery seems to occur when the lesion is one of the visual area or of the post-central convolution. The absence of recovery in lesions of the visual cortex seems to me to be reasonably explained by the regularly patterned impingement thereon of the solitary afferent visual path, which is blocked out by the lesion at its termination, with no alternative path possible. Similarly, I would seek to explain both the disability with spatial relations and stereognostic sense which occur in lesions of the post-central gyrus in man as contrasted with the chimpanzee, and the absence of recovery after such lesions, by assuming a direct impingement and patterning upon the post-central gyrus of the afferents subserving that division of sensibility which Head has termed epicritic sensibility by a solitary path newly developed and peculiar to man.

Graham Brown, in his careful description of the movements which result from cortical stimulation in the limbs of the chimpanzee, takes great pains to emphasize that these movements are entirely different from any movements seen in the natural life of the animal. They have not the complexity of pattern, nor the purposefulness of natural movements. They are simple movements, well-nigh the same as those resulting from the stimulation of a peripheral nerve, whereas he says simple movements are never seen in the natural life of the chimpanzee. He evidently means, though he does not say so, that stimulation of the motor cortex is stimulation of a path passing through the cortex, and that it is not stimulation of a function in a centre in which that function is localized.

In man the cortex of the brain has been experimentally stimulated in many cases where the brain has been exposed by a wound in conscious patients, with the result from the ascending frontal gyrus that crude and simple movements followed as in the ape. The patients experienced a sensation of forced drawing of the limb, which they described as exactly the same as that produced by faradization of a peripheral nerve, and in no way resembling any sensation produced by voluntary movement. Similarly, stimulations of the post-central gyrus produced crude unnatural sensations of tingling, again resembling those resulting from faradization of a sensory nerve, and nothing more than these. One case, however, has been recorded in which the occipital pole was exposed, and the observer states that when the electrodes were applied to the region of the cuneus, crude sensations of light were experienced by the patient, and when the electrodes were passed over on to the outer surface of the lobe, the visual sensations assumed a higher character. This single observation is, however, so out of keeping with the clinical experience of visual hallucinations in connexion with lesions of the outer surface of the occipital lobe, which are invariably crude and unorganized, as to be unacceptable without further experiment.

I submit, therefore, that the evidence brought forward up to this tends to show that the loss of function produced

by local cortical ablation results almost entirely from the blocking of a nervous path which is entering or emerging from that part of the cortex, and that the positive results of cortical stimulation are due to stimulation of this path. Local cortical ablation will produce no loss of function if there is a facile alternative path to or from the rest of the cortex. It will give rise to temporary loss of function if a secondary path is available, and permanent loss of function only when no other path is available.

Lashley has recently made a very interesting series of observations upon the cerebral cortex of rats. From very numerous ablations of the cortex he has found no signs of localization of function, but he has proved that the capacity to form motor habits in these animals is reduced in direct proportion to the amount of cortex removed, and by equal amounts of ablation in any of the different cyto-architectural fields. He concludes that the capacity to learn such habits depends upon the available amount of the cortex as a whole, and not at all upon which region remains after ablation, and that the mechanism of integration is to be sought in the dynamic relations among the parts of the central nervous system and not in details of structural differentiation.

I may here, in passing, refer to Dusser de Barrenne's experiments upon strychnine sensitization of the cortex in the cat and in the macaque. In these animals, of course, removal of the cortex corresponding with the post-central cortex of man produces no loss of sensibility, yet he sought to connect these regions with sensibility notwithstanding, and he found that after painting this region with strychnine solution there was hyperaesthesia of the whole body, but much more marked on the opposite side and towards the periphery of the limbs, that there were signs of increased proprioceptive sensibility only on the opposite side, and that these results were absent when strychnine was applied to any other region of the cortex. It would seem, therefore, that in spite of the negative results of ablations, a sensory path does impinge upon this region of the cortex in the cat and in the ape as it does in man.

I will describe another class of experiments which are of much interest and have a profound bearing upon this subject. They were first performed by Robert Kennedy in 1900. Two dogs were taken and all the nerves of the left forelimb were divided above the elbow. In the one dog the nerves were at once rejoined in proper order. In the other the central end of the musculo-spiral was dissected into four strands and joined to the peripheral ends of median, ulnar, musculo-cutaneous, and musculo-spiral respectively. The central ends of median, ulnar, and musculo-cutaneous were cut off as short as possible and left dead-ended. Both dogs recovered the use of the forelimb perfectly and both recovered in exactly the same time. You will bear in mind that in the second dog all the flexor afferents and efferents had been changed on to an extensor path. On stimulating the motor cortex of this second dog it was found that the well-known region for flexion of the paw was no longer excitable, while stimulation of the extensor region now produced contraction of the flexors and of the extensors with equal facility.

Kennedy thought that he had shown that a given area of the motor cortex could be made to change its function, or rather, that it could be made to take on a fresh additional function by switching on to this area a fresh afferent and efferent peripheral path. His conclusions were much criticized on the grounds that the flexion and extension regions of the dog's cortex are not far enough separated from one another to allow of such absolute statements, and further that Kennedy had not taken sufficient precautions against peripheral regeneration from the stumps he considered dead-ended.

A few years later Osborne and Kilvington repeated these experiments in such a way as to avoid the possibility of these errors. They found it possible to divide the left middle cord of the brachial plexus in the dog, and, cutting the proximal end very long, to pass it under the trachea and unite it to the peripheral end of the right middle cord, also cut very long. The central end of the right middle cord was enclosed in a blind rubber tube to prevent sprouting. This dog recovered well; it could walk and run naturally and could use either forepaw to hold down a bone. A very long time was allowed to elapse after recovery before this dog was examined. It will be observed that the extensor afferents and efferents of the right forelimb had been thrown into the left middle cord and therefore on to the right motor cortex. Stimulation of the right motor cortex now gave movements in both forelimbs. In the left there was extension of paw and flexion of elbow, in the right contraction of the triceps and extension of the paw. Stimulation of the left cortex produced movement in the right limb only, entirely excluding any movement in the triceps or paw extensors. To put it shortly, the cortical points for extension of the right forelimb of this dog had been removed from his left hemisphere and had been implanted in his right hemisphere. The left middle cord was then divided high up and its distal end stimulated, when exactly the same movements occurred as had resulted from stimulation of the right cortex. Experiments were carried out on other dogs in which the left middle cord was sutured to the upper part of the right brachial plexus. Good recovery of function occurred, and the subsequent results of cortical stimulation were in every way parallel to those of the first experiment. Kennedy's results were in every way confirmed.

From these experiments, which Sir William Bayliss considered fundamental in connexion with the function of the cortex, have arisen certain rules. First, if a peripheral mixed nerve is cut the corresponding motor cortex loses its electrical excitability. (This, I submit, is only another way of saying that if you block an efferent path near its periphery there can be no result from stimulating that same isolated path as it leaves the cortex, and I infer from this that the results of stimulation in the motor area are those of stimulation simply of an outgoing path and not stimulation of a centre of function.) Secondly, it does not matter to which area of the motor cortex nor to which hemisphere you transfer your peripheral innervation; complete recovery of function occurs—motion, co-ordination, and sensibility—provided that the path in and the path out are fully restored. (From which I infer that the path is much more important than the whereabouts in the cortex.) Lastly, in this recovery of function the afferents must be all-important. Their functional reconstruction after the disorientations produced by the experiments I have just described must precede the regaining of co-ordinated and ultimately perfect movement, which can take place only by proprioceptive guidance. We have already seen that the only consciousness of movement performed comes from the periphery via the afferents. The unusual patterns from the latter, when a false or ineffective movement is performed and when a free act is being trained in, will apparently guide any part of the cortex to complete functional restitution. There is in the function of movement a running analysis from the proprioceptive system, and sometimes in addition from the visual and auditory systems, which is absolutely essential to this function, and from this fact it is probable that movements and sensibility are not separately represented in the cortex, though the afferent and efferent paths may connect on with the cortex in regions widely apart.

I have already referred to the visual region of the cortex as simply the place of reception of the visual fibres in very regular order. A very great part of this visual cortex may be destroyed in man with little lowering of the visual faculty. A bullet passing through both occipital lobes and causing thrombosis of both calcarine arteries and great destruction of the cortex of the cuneus may leave the impingement of the macular fibres upon the posterior limits of the calcarine fissure and on the posterior pole intact. Central vision remains perfect and the visual faculty is really not impaired at all. There is simply the loss of the peripheral fields. Both in the South African war and in the great war I have seen examples of this occurrence. If the bullet passes farther back and crosses the calcarine ending and posterior pole, there is destruction of much less of the cortex, but there is much more disturbance of the visual faculty, though again only because the very important macular afferents are destroyed. Destruction

one occipital lobe, again, produces no breaking up of visual function. A case illustrating this fact was for many years under my observation. A large tumour with many lobes like a dahlia root was dug out from the patient's left occipital lobe. Arising from the tentorium, it had grown across the occipital lobe and had become superficial in the region of the cuneus. Yet this man had no difficulty in returning to work at a skilled mechanic's bench, at which he has carried on for more than twenty years. He tells me that directly he had learned to dodge his absolute right hemianopia, his filing was just as true and his visual judgement was just as good as before his illness and operation.

Destruction of both occipital lobes causes profound disturbance of the visual faculty even in animals, and in man extensive lesions of the white centres of both these lobes, such as occurs in Schilder's disease, has a similar effect, which increases rapidly as the degeneration extends forwards, though there is no involvement of the cortex—as if the occipital lobes were indeed more closely associated with the visual faculty, afferents apart. I have seen no clinical evidence to connect the outer cortex of the occipital lobes with any higher visual function, nor the cortex of the left angular gyrus with the acceptance of written language or with visual disorientation. Visual disorientation has always, in my experience, resulted from a bilateral lesion of the white matter severing the transcortical path running forward from the occipital lobes. One such case resulted from a bullet traversing the brain from one angular gyrus to the other. There was right hemianopia, but vision was not otherwise impaired. He could see and name every object, but he could never avoid running into the tables and chairs in the ward, and when a handful of money was thrown on the ground and he was placed beside it, though he could name and count the coins and make a correct addition of them, he was unable to find them to pick them up. This patient lived many months in this condition, perishing ultimately from ventricular abscess from a scrap of cloth which the bullet had taken into the brain. The nature of the lesion was verified by necropsy. This patient could not connect his visual impressions with his outgoing executive path because the connecting path in the white centre was cut.

The faculty of hearing is only disturbed in man by a lesion of a very small area of the cortex of the temporal region, and then only when the lesion is bilateral. No case has been recorded in which this narrow bilateral lesion has not seriously impaired hearing. This region, known as Heschl's gyrus, is an architecturally distinct region of the cortex, and it is known to receive the radiation from the mesial geniculate body which presumably constitutes the central auditory path. It is an astonishingly tiny area were it a centre of function for so great a faculty as that of hearing. Heschl's gyrus on the left side is of high importance as subserving the faculty of speech. I submit that the cortex of this gyrus is of high importance in connexion with hearing and speech because it is the sole recipient of the central auditory path, and that it is not a centre of function.

The modern conception of the relations of the brain with the function of language began when Dejerine proved that loss of acceptance of written language on the one hand, and loss of exteriorization of speech on the other, could result from purely subcortical lesions, or rather transcortical lesions, which severed the connexions of the left temporal region with the visual receptive area and with the outgoing path respectively. Subsequent pathological evidence, of which I have seen a great deal, seems clearly to prove that loss of acceptance of spoken language, or "word-deafness," is most commonly due to a lesion of the white matter, undercutting the left temporal region, and so dividing the afferents in the central auditory path, and that it is sometimes due to a lesion of Heschl's gyrus, upon which these same afferents impinge. Inasmuch, therefore, as "word-blindness," "word-deafness," and aphasia result relatively or absolutely as permanent events from local lesions of the brain, they are caused by destruction of afferents and efferents, and not by destruction of centres. I was taken to task by Sir Henry Head some years ago for formulating this proposition, on the ground that in mentioning subcortical lesions I was dealing with matters outside speech in its relation to the cortex. I would explain that I consider that the faculty of speech is not the pouring out, as it were, of water from well-stored cisterns in the cortex; it is a high, delicate, and easily upset faculty, which depends very greatly for its functional stability upon a running analysis of correct execution which we receive with our ears and with the proprioceptors of the articulatory mechanism when we speak, and with our eyes and the proprioceptors of our hands when we write. If the two afferent paths by which this running analysis of spoken speech is carried out are cut across, the pattern of speech rapidly deteriorates; though at first it may be voluble, later it degenerates into a jargon bearing no resemblance to the language originally spoken, and, finally, speech tends to be completely lost. As both these afferent paths seem to enter the cortex in the region of Heschl's convolution, they are frequently involved by lesions of the white matter undercutting the left temporal cortex. This is the only lesion known to cause jargon aphasia, and it is a common lesion causing word-deafness. I have seen this proved at many necropsies. One that occurred in my practice only a month ago may be of interest. This was a woman with a tumour involving the left insular cortex, who had suffered for many months with symptoms of increased intracranial pressure without localizing signs. During the last week of her life, and then only, she developed word-deafness and jargon aphasia, word-blindness and right hemianopia, and became totally aphasic. The brain showed a yellow softening oedema extending backwards from the tumour of the insula throughout the white matter underlying the left temporal and the angular cortex. The whole cortex of the outer surface of the hemisphere was normal.

But apart from lesions involving these afferent and efferent paths, which, I contend, cause such profound disturbance of the speech faculty, there is another matter of profound importance, which, together with the lesions of the paths I have just mentioned, will account for all disturbances of the speech faculty, without reference to local centres of function in the cortex. This is the functional breaking up of the speech faculty when the level of its physiological activity is lowered from any cause whatever, including local lesions involving the anatomical substratum. The more difficult functions, the less deeply impressed functions, the functions acquired late, are lost first and most. The foreign language drops out while the mother tongue remains perfect. Solitary nominal recall set in no pattern to swing it up the hill fails, while the patterns of speech still remain facile. Voluntary speech fails sooner than reflex speech, and the patient, unable to exteriorize any spontaneous speech, may easily repeat any word he hears or copy any writing that he is shown. Visual speech fails early in most subjects, for it is the latest of the speech functions to be acquired. The comprehension of spoken language is the last of all to go, for this is the most deeply impressed and the first speech function to be acquired, and from it all other speech functions are trained in. This breaking up of a faculty with the loss of its elements in order of their depth of impression is known as "diaschisis." This term was introduced by von Monakow years ago to explain the occurrence of temporary "word-blindness," which so often accompanies the aphasia resulting from lesions of Broca's region. The word actually means breaking of the connexions, and I cannot help thinking that von Monakow, in using this term, had in his mind the disruption of the afferent, efferent, and transcortical paths, which I am contending are so important in the production of local loss of nervous function.

The association of the speech faculty with the left hemisphere of the brain does not compel the assumption that centres for that function are situated in that hemisphere in right-handed persons. But the alternative must be that the primary paths—afferent, efferent, and transcortical—must be developed in relation with the left hemisphere alone. The facile and invariable recovery of speech after lesions of the left hemisphere in children at an age when neuroblastic development is active and the laying down of fresh paths is possible favour this alternative. The choice of the left hemisphere is to be connected with that supremacy of the left hemisphere long present in

the human race in its expression of right-handedness. This seemed to be the view of Hughlings Jackson in his oft-repeated remark that he "considered that the right hemisphere was equally important, or even more important, than the left hemisphere, in connexion with the speech function in the right-handed person." Why it should be more important does not seem clear, but for Hughlings Jackson doubtless the right hemisphere would be further removed from the impingement of the tract subserving speech upon the left cortex, and therefore would constitute a realm of more complicated and higher function.

The connexion of the prefrontal lobes with mentality does not seem to rest upon the surest of facts. Mentality should be a function of the nervous system as a whole. Very widely spread destruction or isolation of the cortex anywhere and in either hemisphere will, for a time at least, result in grave depression of this function. What has struck me forcibly in my clinical experience is that lesions of the prefrontal region involving the cortex are so much less potent in this respect than destructive lesions of the prefrontal white centre, extending as these often do backwards to catch the forward fibres of the corpus callosum and part of the radiation from the temporal isthmus, and the obvious inference is that by such lesions of the white matter so much more of the cortex is functionally isolated, so many more of the transcortical paths are severed, and the possibility of compensation by other regions of the cortex is thereby defeated. I have seen the gravest disturbances of mentality from cortical and from subcortical lesions in every part of the brain, but more from subcortical lesions; of all lesions producing mental reduction those of the corpus callosum, however, have been the most striking and constant, and especially when the splenium is destroyed. One can well realize why the great anatomist Willis was convinced that the seat of the soul was in the corpus callosum. He had doubtless seen, as I have seen several times, a lesion of this structure associated with such loss of memory from moment to moment, such disorientations of association in consciousness, the more striking for the complete absence of hebetude, as to convince one for all time of the high potency of transcortical lesions in breaking up higher nervous functions. It is to such transcortical lesions rather than to any cortical lesions that the phenomena of apraxia, agnosia, and disorientation are attributable. Huge lesions of the brain, both of cortex and subcortex, even in the positive regions, are sometimes seen with little disturbance of nervous function. Most of such lesions have occurred in early life, and while neuroblastic development is still active. For example, a man of 24 years of age perished of tuberculous meningitis in my ward at St. George's Hospital. We found a porencephaly involving almost the whole area supplied by the left middle cerebral artery. Yet he was right-handed, and was a skilled artisan, and had shown no signs of a defective nervous system.

In a child under the age of 6 years a lesion involving Heschl's gyrus on the left side produces no permanent aphasia, but complete restoration of speech occurs provided sufficient intelligence remains. Nor does a lesion of the parietal region produce the very permanent defects of sensibility which are seen in the adult. This is another way of saying that, provided sufficient healthy cortex is available, and provided neuroblastic development be active, the paths which subserve these late developing functions will be redeveloped in connexion with other regions of the cortex. For in the brain the later developing structures are so much determined by the development of function, and for this reason it is indeed probable that human brains are not all structurally the same as regards details of anatomy subserving the higher and later developed functions.

It may be argued with justice that the different structure of the several parts of the cerebral cortex suggests an especial function for each region. But there are more than forty such areas which have been mapped out as architecturally distinct, the fascinating study of which has not yet thrown any light upon the part which each area may take in the make-up of nervous activity as a whole.

The cortex of the cerebellum shows no more localization of function than that determined by the bilateral symmetry of the body. The limbs of the same sides are more affected by lesions of the lateral lobe; the head, neck, and trunk more by lesions of the vermis. The lability and the compensatory possibilities of this cortex are most remarkable, for it may be said of the symptoms resulting from an acute and terminable lesion affecting chiefly the cortex, severe though these always are, that they invariably recover. It is of especial interest that irritative lesions of one of the chief afferents to the lateral lobe—namely, the vestibular nerve—produce exactly the same symptoms as does an acute lesion of the lateral lobe. For example, acute vestibulitis is only distinguishable from an acute vascular or inflammatory lesion of the lateral lobe by the deafness due to a simultaneous involvement of the cochlea, when this is present. When, however, the white connexions are destroyed, even locally and by small lesions, permanent symptoms result, and these are sometimes of local distribution. Thus, one may see the eyes, or speech, or the trunk, or the upper limb, but very rarely the lower limb, exclusively or predominantly affected. Any localization of function that there is in the cerebellum seems to be in the white matter and to result from destruction of the afferent and efferent paths of local direction.

The oculomotor nucleus has been resolved by anatomists into a very definite series of paired and unpaired subnuclei, and an attempt has been made to invest these subnuclei with local function. The results have not proved of clinical value, and even hypothetical "supranuclei," which are supposed to rearrange the cerebral incitations for the oculomotor nucleus, have been called upon to help the matter out. Such localization seems unnecessary and untenable on physiological grounds; for the oculomotor nucleus is nothing more than one region in the path subserving the movements of the eyes where a resorting of nerve fibrils occurs from the terms in which we use our eyes into terms of the peripheral nerves. There is, in addition, the path of the metameric light reflex thrown in.

Now we know well that the outgoing incitations from the brain to the oculomotor nucleus arrive at that nucleus in terms of conjugate upward movement, downward movement, and lateral movements and convergence; for all ablations and excitation of the brain prove this. Moreover, lesions just in front of the posterior commissure which do not touch any part of the oculomotor nucleus will cause paralysis in each or all of these terms, according to the position and extent of the lesion, and in these terms only. The path as it descends lies lateral to the nucleus and its elements turn in to the nucleus in known order: first those for upward movements, then those for downward movements, then those for convergence, and, lastly, those for lateral movements. It is this turning of the several elements of this path at different levels which determines local loss of function in terms of vision when there is a local lesion of the oculomotor nucleus, and not because a function is located in the grey matter thereof. Actually a lesion of the oculomotor nucleus, or of any other nucleus or mass of grey matter, potentially creates three lesions: the first in the incoming path, for this does not end abruptly; the second in the convergence, and this will produce irregularity, loss of balance, and inco-ordination in the result; the third in the outgoing path, for this does not gather abruptly.

Conclusions.

1. In the consideration of a faculty of the nervous system it is just to locate the function in the whole of the anatomical substratum connected with it, and not in any one part of it. The substratum is a path commencing in the periphery, entering the central nervous system and converging with other paths which modify its function at each convergence; entering the cortex of the brain and spreading widely with infinite convergences and modifications of function and gathering again thence to return to the periphery. In so far as this path is compact and single it is vulnerable to local destructions. Inasmuch as it is diffuse or duplicated in another place, it is not vulnerable. In the cortex of the brain the paths soon become diffused. Keep away from those regions of the cortex through which the compact single paths to and from the periphery are known to pass and ablations will produce no loss of function, for the path is here too widely spread and the

function too widely distributed to be influenced by small local loss; nor will such terms as "annexes," "association areas," or the word "psycho" prefixed to any word that you may wish satisfy us, in the absence of any definite evidence, as to the functions of the highest product of evolution—the cerebral cortex.

2. The chief difference between the brain of a bird, in which no ablation produces local loss of function, and that of a mammal, in which ablations in certain definite regions produce temporary loss of function, and again between these two and the brain of man, in which certain ablations produce permanent loss, seems to lie in the progressive development as one ascends the animal scale of direct and compact paths to and fro between the cerebral cortex and the periphery, and these paths tend to become exclusive as regards a definite function in the highest animal; whereas in the less high animal the indirect and ancestral path is still utilizable when the direct path is damaged. The brain of all the higher animals must be built up structurally and functionally more or less upon the same plan.

3. The experimental physiologists of to-day have laid down that the motor cortex is only so-called by them because it is more excitable than the rest of the cortex, and that even in this region lability of function, facilitation, and deviation of response are much more characteristic features than is localization; and that there must be other mechanisms than this precentral cortex which act directly upon the lower motor mechanism by means of direct descending fibres; and that normal motor activation takes place through descending fibres from many parts of the cortex; and that in complex motor activity the cerebral cortex acts as a whole, though the activity of some parts of it may be accentuated and of other parts depressed; and that the activity of any one part of the cortex is conditioned by the balance of innumerable activities which proceed from other parts of the cortex. (I have here used the words of Graham Brown.) The physiologists have abandoned the localization of function within the cerebral cortex, and this position is in accord with the clinical evidence in man.

4. The past century has seen the question of localization of function in the higher parts of the nervous system introduced by Gall and the phrenologists in 1810; denied by Flourens in 1824 from his ablation experiments upon the bird's brain, for he contended that the brain represented the living animal as a whole, and not in terms of separate parts or functions; reintroduced by Hitzig and Broca in 1860, and carried to a high degree of theoretical detail by the later Victorian authorities, amongst whom, however, Hughlings Jackson stood conspicuously apart, for his theory of the nervous system essentially denied separation of function in its highest parts; again gradually changing in the early part of the twentieth century for a vague and indefinite localization or for a localization of function in the conducting paths only, as adopted by Sir Henry Head in 1924; and finally rejected so far as the cerebral cortex is concerned by both physiologists and clinicians at the present time.

5. It is obvious that each region of the cerebral cortex must be of equal functional importance in the make-up of the perfect animal, yet it is difficult to give up the belief that those regions of the cortex which immediately border upon the junctions of the cortex with the sensory path, the visual path, the auditory path, and the pyramidal path, are more especially connected with the functions these paths subserve. But it must be carefully borne in mind that the evidence in favour of this belief, upon the experimental side, is solely the facilitation experiments of Graham Brown, while upon the clinical side there is no certain evidence whatsoever.

CONTROL OF OCULAR DISEASE OF VENEREAL ORIGIN.

A SURVEY OF THE METHODS EMPLOYED IN SCOTLAND.*

BY

GEORGE MACKAY, M.D., F.R.C.S.Ed.,

CONSULTING SURGEON TO THE EDINBURGH ROYAL INFIRMARY, ROYAL BLIND ASYLUM, ETC.

THE disastrous consequences to humanity which have resulted from venereal disease are well known and universally deplored. Laudable efforts have been made by the medical profession to counteract this evil. An International Ophthalmological Congress appears to be a suitable occasion on which to present a survey of what has been done in recent years in Scotland for the control, by preventive measures as well as by actual treatment, of the ocular disturbances which are associated with venereal disease.

I.—THE CONTROL OF PURULENT OPHTHALMIA.

In 1879, by the discovery of the gonococcus which bears his name, Neisser laid the scientific basis for the treatment of this purulent inflammation.

In 1880 Credé of Leipzig introduced the prophylactic method of dropping a nitrate of silver solution (2 per cent.) into the conjunctival sac of newborn infants, and thereby at once reduced the incidence of ophthalmia neonatorum in a remarkable degree. His method was largely adopted throughout the civilized world, with immense benefit.

In 1901 I had the honour to be appointed, in succession to my revered master the late Dr. Argyll Robertson, to undertake the duties of ophthalmic surgeon to the Royal Blind Asylum in Edinburgh, and in my first annual report, submitted to the managers on December 1st, 1902, I passed in review the causes of blindness in 92 inmates—25 males and 67 females. I drew attention to the fact that nearly one-third—31.8 per cent.—of all the cases admitted owed their blindness to purulent conjunctivitis, which had been permitted to occur in newborn children, generally for want of proper precautions which should have been taken at birth. The directors sent a copy of this report to all the dispensaries and local medical institutions in Edinburgh. Representations made by ophthalmic and gynaecological colleagues in other parts of Scotland lent their aid towards disseminating fuller knowledge, but ophthalmia neonatorum still remained of frequent occurrence.

In 1907 the British Medical Association appointed a committee to investigate and report upon the prevalence and prevention of ophthalmia neonatorum in the United Kingdom. The report was actually prepared by the late Mr. Sydney Stevenson of London, who was chairman of the committee, and was issued in 1909. It revealed the fact that in the various blind asylums and schools the proportion of patients whose blindness was due to ophthalmia neonatorum formed an average of about 35 per cent., and that there had been no certain diminution of the disease during recent years. Attention was also drawn to the fact that numerous cases had been known to occur among patients attended by medical practitioners, as well as in those attended by midwives only.

In 1911 the Local Government Board (now the Department of Health for Scotland) instructed Dr. T. F. Dewar, one of their medical officers, to investigate the position in Scotland. In the report which he submitted in 1912 Dr. Dewar estimated that approximately 500 cases of ophthalmia neonatorum occurred in Scotland annually. Of these, from 30 to 40 suffered some impairment of vision, and from 5 to 10 became economically blind. He found that medical opinion as to making ophthalmia neonatorum a notifiable disease was not unanimous, partly for sentimental reasons, but to some extent owing to a prevalent belief that under the existing conditions the disease was already becoming less frequent in Scotland. He pointed out the need for midwives being instructed to play their part more efficiently in the prophylactic treatment. Following the example of England, some local authorities in Scotland had already adopted compulsory notification, and after the circulation of Dr. Dewar's report the number of authorities which voluntarily adopted the action rose from 26 in 1912 to 40 in 1916.

In 1915 a Midwives Act for Scotland was passed, and under the rules drawn up by the Central Midwives Board for Scotland it became incumbent upon every midwife to call in to her assistance a registered medical practitioner

* This paper was contributed to the proceedings of the Thirteenth International Ophthalmic Congress, held at Amsterdam, September, 1929, and is published by permission of the Editorial Committee.

if she observed inflammation of, or discharge from, the eyes, however slight. Further, if any purulent discharge from the eyes was seen commencing within twenty-one days from the date of birth, and medical assistance had not been obtained, it was her duty to inform the local authority.

In 1917 the development of child welfare and maternity schemes brought into existence another most valuable and beneficent organization. Strengthened by the strong recommendation of the Departmental Committee on the Welfare of the Blind [see report on July 20th, 1917 (Cmd. 8655)] that the notification of ophthalmia neonatorum should be made compulsory, the Local Government Board for Scotland issued the Public Health (Ophthalmia Neonatorum) Regulations (Scotland) 1918, which took effect as from November 1st, 1918. The covering circular issued with the regulations pointed out that mere notification without treatment was of no practical value, and impressed on local authorities the need for ensuring that skilled assistance should be available in every case as soon as it was notified.

On July 16th, 1921, the Scottish Board of Health issued a further circular on the question of ophthalmia neonatorum. It did not enforce, but it recommended, the instillation of a 1 per cent. solution of silver nitrate into the eyes of all newly born infants. It also stressed the need for hospital treatment in all but the mildest type of cases, and called for reports to be made to the Board in every case in which in the opinion of the medical officer of health there occurred appreciable loss of vision. The particulars to be supplied in these reports were as follows:

1. Name of case.
2. Address.
3. Date of birth.
4. Date of notification of ophthalmia neonatorum.
5. By whom confinement attended.
6. Subsequent medical attendant (if any).
7. Where treated.
8. Date of removal to hospital if so removed.
9. Date of discharge from hospital or of cessation of treatment.
10. Nature of infecting organism (if ascertained).
11. Condition as regards vision at end of treatment.
12. Living or dead.
13. Remarks.

On receipt of such reports investigation is made into the circumstances of each case by one of the department's medical officers. Special attention is directed not only to the clinical side of the case, but also to (1) the treatment of the eyes at birth, (2) the question of delay (if any) in notification by the doctor or midwife in attendance, and (3) the question of delay in the provision of special treatment. Attention is drawn to any cases in which there has been apparent laxity. Where a midwife has been at fault the local authority may, if the circumstances warrant, report her to the Central Midwives Board for Scotland. The penalty for gross negligence or carelessness is suspension or removal from the Midwives' Roll. Under the rules made by the Central Midwives Board for Scotland for regulating the practice of midwives, a midwife is required so soon as the child's head is born to cleanse the eyelids and instil one or two drops of a 1 per cent. solution of silver nitrate.

After three years' further experience the Scottish Board of Health were not satisfied that all that could be done for ophthalmic cases was being done by local authorities, and they accordingly authorized the issue of another circular on January 11th, 1924. This circular again emphasized that the disease was preventable, and that its disabling effects could be avoided by prompt and adequate measures of treatment. It pointed out that satisfactory arrangements for hospital treatment could not be improvised on the occurrence of a case, and local authorities were called on to make, as part of their maternity and child welfare schemes, arrangements with suitable hospitals possessing adequately trained staffs, in order that any case occurring might receive treatment immediately. It is satisfactory to note that, as a result of this circular, practically all local authorities administering maternity and child welfare schemes made arrangements on the lines indicated. Maternity and child welfare schemes are now (1929) in operation in areas comprising 93 per cent. of the population of Scotland.

The following table shows the trend of notification since notification was made compulsory in Scotland in 1918, and also the number of cases removed to hospital, and the number of cases resulting in appreciable loss of vision reported to the department since 1921, when reports were first called for.

TABLE I.—*Ophthalmia Neonatorum (Compulsory Notification—all Scotland).*

Year.	Number of cases of ophthalmia neonatorum notified.	Number removed to hospital.	Number of cases reported to department resulting in appreciable loss of vision.
1919	1,431	162	—
1920	1,871	127	— Reports not demanded at that time.
1921	1,697	115	—
1922	1,485	71	5
1923	1,390	105	7
1924	1,289	119	15 Probably due to delay in notification or sending to hospital.
1925	1,246	115	3
1926	1 295	140	2
1927	1,311	124	15 (4 from Eyemouth, 4 from Lanarkshire).
1928	1,305	154	4

The decrease of 30 per cent. in the number of notifications between 1920 and 1927 indicates a measure of success in the preventive action taken. The numbers removed to hospital do not show much variation over the period recorded. It does not necessarily follow, however, that there has been no reduction in the number of severe cases necessitating special treatment, as it may well be that, with the total number of cases showing a substantial decrease in the later years, a proportionately greater number are given the advantages of hospital treatment, which is now more readily available than it was in the earlier years of the department's administrative action in connexion with the disease. It is possible that the desire to secure careful treatment of all cases of conjunctivitis in the newborn may have resulted in the notification of some cases of conjunctival irritation or catarrh unconnected with venereal infection. This is all to the good, though it may make the statistical position somewhat more indefinite.

As regards the cases reported to the department as resulting in appreciable loss of vision, the following table shows the effect of the disease on the vision and whether the gonococcus was the infecting organism.

TABLE II.—*Summary of Cases of Ophthalmia Neonatorum reported to the Department as resulting in Appreciable Loss of Vision in all Scotland.*

Year of child's birth.	Total No. of cases reported	Analysis of cases resulting in impairment of vision.			Cases not resulting in loss of vision finally.	Cases due to gonococcal infection.	Cases where infection was not gonococcal or not ascertained
		Total blindness.	Partial blindness.				
			Both eyes.	One eye.			
1922	5	3	—	2	—	4	1
1923	7	—	2	4	1	3	4
1924	15	3	1	11 (1 died)	—	9	6
1925	3	1 (died)	—	2 (died)	—	1	2
1926	2	—	—	2	—	2	—
1927	15	1	4	8	2	3	12
1928	4	2	—	—	2	2	2
Total	51	10	7	29	5	24	27

The relatively large numbers reported in 1924 and 1927 were due to the occurrence of groups of cases in certain areas. It appears that in 1924 they were mainly due to delayed notification or delayed admission to hospital. In 1927 four cases occurred in one village, and four in another county due to inefficient cleansing or careless handling of contacts. The moral of such outbreaks is that the best organization will fail unless backed up by constant vigilance and conscientious performance of duty by all concerned. But where these conditions are secured the results are very gratifying.*

In the Edinburgh area the organization, supervised by Dr. Robertson, the principal medical officer, and his staff, is very complete and effective, and I am happy to be able to state that in this area there has been no case of blinding by ophthalmia neonatorum within the past five years.*

II.—THE CONTROL OF VENEREAL DISEASE IN GENERAL.

There is no compulsory notification of venereal disease (except ophthalmia neonatorum) in Scotland. Its control is thus much more difficult. It rests with the patients themselves or their medical advisers to avail themselves of the opportunities for diagnosis and treatment supplied by the public authorities or by qualified private practitioners.

In 1919, under compulsory regulations of the Local Government Board which applied to the whole of Scotland, the public health authorities of the city of Edinburgh reorganized the venereal disease department under the supervision of the medical officer of health, and in the same year Dr. David Lees was appointed as its chief director.

By arrangement with the Royal Infirmary of Edinburgh, the largest hospital in the city (which is maintained by voluntary subscriptions), accommodation was found for a special clinic for adults within that institution, but the cost of the maintenance of this department is borne by the public funds, one-fourth being raised by assessment upon the citizens and three-fourths by grants from the Government Exchequer. This plan has encouraged the attendance of patients of the hospital class, since it largely avoids the publicity and opprobrium attaching to their appearance at a separate institution, and it has brought the special staff, and their services for diagnosis and treatment, into close touch with the requirements of patients in all the medical and surgical wards of the Royal Infirmary. It has also facilitated the teaching of students in our great medical school.

The public health authorities have made further provision for nursing mothers and infants with ophthalmia neonatorum, and young boys and girls requiring hospital treatment—for example, cases of interstitial keratitis or vulvo-vaginitis. These are admitted to another civic hospital, where they receive treatment with a minimum of publicity. Every effort is made to investigate sympathetically the circumstances of the families from which these patients come. Thus, both the father and other children are inspected with a view to their protection and treatment.

In the absence of compulsory notification reliable statistics showing the relation between syphilis and eye diseases cannot be prepared. Cases first seen at the ophthalmic wards and eye dispensaries are usually sent on to the venereal disease department for a confirmatory diagnosis and for subsequent treatment. The figures tend to overlap. The cases dealt with in private are not recorded.

I am indebted to Dr. David Lees, the energetic head of the venereal disease clinic, for the appended table, which shows the total number of cases of syphilis attending his clinic for treatment in the last quinquennial period, and the number which resulted from inherited syphilis.

TABLE III.—*Syphilis.*

Year.	Males.	Females.	Total.	*Inherited Syphilis.*
1924	522	784	1306	372
1925	489	750	1239	312
1926	460	811	1271	232
1927	616	724	1340	313
1928	687	752	1439	284
	2775	3821	6595	1573

Some of these were not cases of gross illness. In some the eyes were not affected. The apparent increase in the total number treated in 1928 may only indicate that a closer scrutiny is being maintained.

The above table shows that the cases seen between the years 1924 and 1928 numbered 6,595. Of these, about two-thirds (that is, about 4,400) came from Edinburgh, the remainder from surrounding districts. Of the Edinburgh cases, 354 were due to inherited disease. Of these, 136 suffered from interstitial keratitis and about 40 more had some eye trouble—for instance, iritis or choroiditis, or optic atrophy.

At the Royal Blind Asylum School in Edinburgh, where the Wassermann test is now systematically applied to every applicant for admission, of 67 children examined in a period of six months, 21 were found to be suffering from inherited syphilis, both clinically and serologically.

My colleague Dr. Lees is, however, confident that some progress has been made—that there is a reduction in the number of fresh infections; a definite reduction in the number of cases of newly born children suffering from syphilis, and in the number of ante-natal and neo-natal deaths due to syphilis. He believes that the efforts which are at present being made, and especially the ante-natal treatment in association with maternity hospitals initiated by the late Dr. Ballantyne of Edinburgh, are lessening, and will in future appreciably lessen, the incidence of inherited syphilis. If, in addition, children born of infected parents are kept under observation for a considerable period after birth, as they now are through the child welfare organizations, there ought to be a decided decrease in the number of cases of ocular disease from inherited infection.

Time and space do not permit of my giving details of the organizations which are dealing with venereal disease in other parts of Scotland, but the arrangements in Glasgow, Dundee, Aberdeen, and the larger towns are on much the same lines as those already described, and good results are being obtained.

Our health authorities are seeking improvement in other directions, through better housing, by the promotion of temperance, and by instruction in the laws of health. Their exertions are aided by social efforts to promote morality. In recent years the health authorities for Edinburgh endeavoured to secure fuller powers for the control of venereal disease, including compulsory treatment, but the proposal was rejected by Parliament. It is understood that a fresh effort is being made in Glasgow and the West of Scotland. We have a large maritime population. In 1925 an international agreement relating to the treatment of venereal diseases amongst seamen was ratified by His Majesty King George on behalf of Great Britain and Northern Ireland. Under this agreement the contracting parties undertake that facilities shall be available, at each of their chief sea and river ports, for the gratuitous treatment of merchant seamen, without distinction of nationality, and such facilities are to include out-patient treatment, in-patient treatment where necessary, and the provision of sufficient medical supplies to carry out necessary treatment during the voyage to the next port of call. The agreement also requires that each patient shall be supplied with a card for the purpose of providing a brief record of the diagnosis of the case, the treatment given, and the treatment to be followed during the course of the voyage.

It will be interesting to compare our experiences with those of other countries as regards the methods of control which some have already enforced upon their people. We invite international co-operation in combating an international infection.

* Through the courtesy of Dr. T. Y. Finlay, chmical medical officer in charge of the Edinburgh *maternity and child welfare scheme*, I was able to present to the congress a table showing the total number of cases of ophthalmia neonatorum *notified in Edinburgh* between the years 1920 and 1928, the relative number of cases treated in hospitals or at home, and the results of treatment. A further table illustrated the number of cases notified in the year 1928, showing the actual interval which elapsed between birth and the notification of the appearance of conjunctivitis, and how the cases were dealt with and the results of treatment. Space does not permit of the reproduction of these tables here, but they will be gladly supplied on application to Dr. Finlay, c/o The Medical Officer of Health, Johnstone Terrace, Edinburgh, or to myself.—G. M.

ATYPICAL ENTERIC INFECTIONS.

A REPORT OF FOUR CASES.

BY

J. D. ALLAN GRAY, M.B., B.Sc., M.R.C.P.ED.,
ASSISTANT CITY BACTERIOLOGIST, LIVERPOOL.
(From the Bacteriology Department, Edinburgh University.)

BACTERIOLOGICAL investigation of material obtained at necropsies in the Royal Infirmary, Edinburgh, have recently demonstrated the presence of organisms of the enterica group in cases which during life have presented quite atypical features. The object of the present communication is to illustrate by means of four cases the apparent frequency of such infections (see Billet and others, 1910). In each of the cases the diagnosis of enterica was not made until specimens obtained at the necropsies were examined bacteriologically, although in one case the "step-like" rise of temperature had aroused clinical suspicions of enteric infection.

Such atypical cases may be either primary infections or acute exacerbations in a chronic carrier. They are liable to be diagnosed incorrectly, and the consequent absence of suitable precautions would then promote the spread of the infection.

As emphasized in the report by Dr. Brincker on the outbreak of paratyphoid fever in London in 1928, infections with certain organisms of the paratyphoid group were comparatively rare in Britain before the war. Since then, however, large numbers of individuals, after a sojourn in areas where such infections are endemic, have become carriers. The temporary carrier, convalescent from a recognized attack of enteric fever, is likely to be watched by careful sanitary authorities, but chronic convalescents, and specially paradoxical and transitory carriers, by the intermittent discharge of pathogenic organisms for many years, constitute a serious potential danger to the community. The length of time during which such carriers harbour the bacilli of course varies, and depends on the establishment of chronic lesions (Sacquépée, 1910). That the number of such individuals discharging these organisms is relatively great is supported by the demonstration of *B. typhosus* in Belfast sewage by Wilson (1928) and of *B. paratyphosus* B Schottmuller in Edinburgh sewage by myself in 1929. The comparative freedom of these towns from enteric fever during the investigations renders it probable that these findings were due to the presence of resident carriers or unrecognized cases of the disease.

CASE I.

Clinical History.—A painter, aged 63, was admitted with a three days' history of abdominal pain, diarrhœa, and the vomiting of clear and later a dark green, fluid; he was stated to have been "pale and ashen," and to have had a temperature of 99° F. two days before admission.

On admission he was moribund; temperature 98.6°; pulse feeble 80; respirations 28. He was sweating slightly, but there was no rash. He complained of pain, constant and gnawing, over the whole abdomen, but not radiating in any special direction. Apart from slight rigidity over the upper part of the right rectus muscle the abdomen was flaccid. He died the following day.

Previous History.—Similar but less severe attacks had been experienced every few months for some years, thirty years ago he had travelled widely as the mate of a merchant ship. There was no history suggestive of enteric fever in the patient or his family.

Post-mortem Findings.—The peritoneal cavity, stomach, and the large and small intestines were all healthy, but the liver was pale and congested. The gall-bladder was not thickened or enlarged but contained rather thick opaque and greenish bile. The spleen was not enlarged and the kidneys were congested and pale. There was no pneumonia.

Bacteriology.—The bile yielded an almost pure growth of an organism identified by agglutination and agglutinin-absorption tests as *B. paratyphosus* B Schottmuller, and the same organism was isolated from the intestinal contents.

Discussion.

The clinical data and bacteriological findings suggest that the case was one of acute exacerbation of a chronic cholecystitis due to *B. paratyphosus* B Schottmuller.

In the course of enteric fever the causative organisms are always present in the gall-bladder (Chiari, 1884, and Pratt, 1901). Owing to the invariable bacteriæmia in the early stage, the avenue of infection to the viscus is generally thought to be the hepatic circulation. Blumenthal (1907), Laubenheimer (1908), Garbat (1916), and Kuester (1918), however, have all given evidence in support of the possibility of an ascending infection from the duodenum, and Nichols (1917) believes in a descending infection from the liver. Pratt (1901) divided cases of typhoid cholecystitis into two classes: (1) cholecystitis secondary to typhoid enteritis, and (2) cholecystitis due to a primary infection of the gall-bladder. Experimentally, cholecystitis has been produced by many workers by the intravenous inoculation of typhoid bacilli (Rosenow, 1916).

That normal bile is not a suitable pabulum for the growth of organisms was shown by Förster, and, later, by Drennan (1922) and Johnson (1925). Drennan, however, showed that the inhibitory power of the bile was annulled by the addition of albuminous material sufficient to render the final concentration of bile not more than 70 per cent. In cases of enteric fever the albuminous material is supplied by the inflammatory exudate from the gall-bladder and bile ducts.

In most cases this "cholecystitis typhosa" subsides within at most a year of the recovery of the patient, but in about 2 to 5 per cent. of cases the bacilli persist in the gall-bladder for many years, the subjects then becoming chronic carriers of the organism. It is impossible to determine the date and primary site of the infection in the case recorded above. If infected abroad, the patient must have carried the bacilli for at least thirty years—most probably in the gall-bladder. Cases in which an attack of enteric fever preceded the detection of the carrier condition by forty-six and fifty-two years respectively have been recorded by Bolduan and Noble, and by Gregg. Actual cholecystitis—that is, clinical or pathological evidence of inflammation of the gall-bladder—following attacks of enteric fever by periods varying from seven to forty-one years have been recorded by Miller (1898), Hunner (1899), Dean (1908), Clairmont (1911), and Pomeroy and Shen (1925). Dean's case resembles the case recorded in being one of remittent biliary colic.

CASE II.

Clinical History.—Housewife, aged 76, admitted with five days' history of intermittent severe epigastric pain and vomiting occurring several hours after meals; the bowels were irregular and the stools contained blood. Similar, but less severe, attacks had been experienced for some years.

On admission she was acutely ill, but there was no jaundice or rash; the whole abdomen, though flaccid, was tender, especially in the epigastrium and over the gall-bladder. The temperature, which had been 99°, became subnormal; but on the second day after admission it rose to 103°, became swinging, and the patient died the following day with a temperature of 104°.

Previous History.—The patient had never been abroad, and there was no history suggestive of enteric fever in the patient or any of her relatives.

Post-mortem Findings.—The peritoneal cavity, liver, and stomach were all healthy; the gall-bladder contained two conical stones, each one inch in length and lying with the flattened surfaces apposed. The mucosa of the gall-bladder was thickened owing to fibrosis and recent inflammation, and, in apposition to the space between the stones, there was a deeply ulcerated and nearly perforated gutter round the whole circumference of the viscus. The gall-bladder was fibrosed and adherent to the liver tissue; the ducts were patent. The first part of the duodenum presented a stellate scar, and the second part a small acute ulcer. The lower end of the ileum was slightly congested, but there was no swelling or ulceration of the lymphoid tissue. The transverse, descending, and sigmoid colons all showed numerous ulcers. Each ulcer was a quarter to half an inch in diameter, and had raised edges and a necrotic floor. The spleen was small, and the pulp dark and diffluent. The other viscera were comparatively healthy.

Bacteriology.—An organism identified by agglutinin-absorption tests as *B. paratyphosus* B Schottmüller was isolated from the ulcers in the duodenum and large bowel, the intestinal lymph glands, the gall-bladder, and the interior of one of the gall-stones. In the spleen the same organism was present in pure culture.

Discussion.

This case is similar to the first, but with the addition of a concomitant cholelithiasis and generalized infection in which the situation of the ulcers was quite atypical. It seems probable that this case was an old-standing infection, since the demonstration of *B. paratyphosus* B Schottmüller in the interior of one of the stones is strong

evidence that it was the primary etiological agent concerned in the production of the stone. It is unlikely that enteric organisms penetrate preformed gall-stones (Pratt, 1901), and from the experiments of Dmochowski and Janowski it has been deduced that "in clinical cases where the typhoid bacillus is present alone it is improbable that other organisms were present at an earlier date." Presumably, therefore, the patient was a chronic carrier, developed gall-stones, and finally succumbed to an acute generalized infection. Such is undoubtedly a rare sequence of events, as Kuester did not observe a single disturbance which could be ascribed to the enteric organism in 800 chronic carriers kept under observation for two and a half years, and, according to Zinsser, carriers appear to possess a degree of resistance to second attacks higher than even that of the individual who recovers completely.

In addition to the usual tendency to obstruction to the flow of bile in all cases of cholecystitis, the presence of *B. typhosus* appears to have a special faculty of precipitating cholesterol from bile salts (Gilbert and Fournier, 1897: Richardson, 1899; Cushing, 1899; Doerr, 1905; and Exner and Heyrovsky, 1908), although Novzari (1928) does not believe that such infection predisposes to cholelithiasis. Pratt (1901) and Hertz and Adams (1909–1910) have recorded the formation of cholesterol stones containing *B. typhosus* within eighteen and sixty-eight days respectively from the apparent onset of typhoid fever. On the other hand, Dowd (1911) has reported the demonstration of *B. typhosus* in stones thirty-two years after typhoid fever.

CASE III.

Clinical History.—A brewery worker, aged 35, was admitted with a history of nausea for twenty-four hours and the sudden emesis of dark blood-stained material on three occasions on the day of admission. The bowels were regular and there had been no loss of weight.

On admission examination of the abdomen was negative except for slight tenderness and rigidity in the epigastrium. The spleen was not palpable and the stomach and liver were normal in size. Temperature 97.0°; pulse 120. The patient became rapidly weaker, and died on the fifth day after admission. The temperature showed a "step-like" rise, but never rose about 100.2°. There was no diarrhoea, although on the day before death the stools resembled the "pea-soup" variety.

Previous History.—Apart from being in France during the war, the patient had never been abroad, and there was no history suggestive of enteric fever in the patient or any of his relations.

Post-mortem Findings.—The peritoneum was healthy. The stomach contained bile-stained fluid and showed submucous haemorrhages. The small intestine was slightly inflamed, and although one of the Peyer's patches was ulcerated, there was no swelling of the lymphoid tissue. The naked-eye appearances of the large bowel and gall-bladder were healthy, but the liver and kidneys showed acute parenchymatous degeneration. The spleen was small, dark, and diffluent.

Bacteriology.—*B. paratyphosus* B Schottmüller was isolated from an emulsion of the crushed wall of the gall-bladder, the organism being identified by agglutinin-absorption tests. The heart blood, spleen, and bile were all sterile, and no non-lactose-fermenting organisms were isolated from the ileal ulcer, ileal contents, and emulsion of the liver. Serum obtained from the cadaver did not agglutinate a known *B. paratyphosus* B emulsion at a dilution of 1 in 25 or higher dilutions.

Discussion.

The case is peculiar in that, although the heart blood, spleen, bile, and intestinal contents did not show evidence of the presence of *B. paratyphosus* B Schottmüller, the organism was found in the gall-bladder wall. The examination of the latter was made in view of the fact that in cases of cholecystitis Rosenow (1916) and A. L. Wilkie (1928) have isolated from the wall of the gall-bladder a streptococcus which could reproduce the disease in animals.

The presence of the organism in the wall, and its absence from the lumen of the gall-bladder, may be accounted for by the supposition that the viscus contained a percentage of bile too great for the viability of organisms. The failure to demonstrate *B. paratyphosus* B Schottmüller in the ileal ulcer and contents may have been due to the fact that in the interval between death and necropsy (eighteen hours) there occurred an overgrowth of lactose-fermenting organisms which masked the presence of enteric organisms present at the time of death. On the other hand, the patient may have been carrying the organisms in the wall of the gall-bladder, which, prior to the death of the patient, was not discharging them into the lumina of the gall-bladder and intestines. This would be in keeping with the normal appearance and sterility of the bile. Pratt (1901) stated that in two cases he had found the enteric organism in the gall-bladder, but not in the heart blood, spleen, liver, and kidney. Fletcher and Lesslar (1925), who recorded a case of typhoid septicaemia without typhoid ulcers, regarded as an open question whether their patient was a chronic carrier in whom the septicaemia resulted from an old focus in the gall-bladder or whether the latter had become recently infected as part of the general septicaemia.

CASE IV.

Clinical History.—A domestic servant, aged 21, was quite well till a fortnight before admission, when she developed a "cold." A week later, owing to constipation, she took large doses of salts, since when she had had diarrhoea. For two days prior to admission generalized abdominal pain was felt, especially on the right side. There was no vomiting.

On admission the tongue was furred; the whole abdomen was tender, and in the lower part slightly resistant. There was no rash or recognizable enlargement of the spleen. The temperature was 102°. The abdomen was opened, and, as no pathological condition was found, was closed immediately. The temperature swung between 99.6° and 103.6°. Blood withdrawn two days after admission gave a pure culture of *B. typhosus*, and the serum agglutinated that organism in dilutions up to, but not higher than, 1 in 30. The urine (catheter specimen) was sterile on culture, but contained a few epithelial and red blood cells. The patient became gradually worse, and died four days after admission.

Previous History.—The patient had never been abroad, and there was no history suggestive of enteric fever in her or in any of her associates.

Post-mortem Findings.—The peritoneal cavity and stomach were healthy. Small, deep, punched-out ulcers, swelling of the Peyer's patches, and congestion of the surrounding mucosa were seen in the ileum, but there were no ulcers in the duodenum, jejunum, and large intestine. The liver showed advanced fatty degeneration but no necrosis, and the gall-bladder was healthy. The size and consistency of the spleen were normal. The kidneys showed fatty degeneration. There was no pneumonia.

Bacteriology.—*B. typhosus* was isolated in pure culture from the heart blood, spleen, liver, and bile, and from among lactose-fermenting organisms in the gall-bladder wall and caecal contents.

Discussion.

The clinical data and bacteriological findings suggest an acute primary infection, and illustrate how such a condition may simulate an acute abdominal lesion—for example, acute appendicitis. The ulceration of the ileum indicates that the condition had reached at least the eighteenth day, and yet the patient went about until within six days of her death. "Some of the most fatal cases have been those in which the patient was able to keep his feet with comparatively little inconvenience until the end of the third week" (Kerr, 1920).

DISCUSSION OF THE CASES.

The clinical picture presented by the four cases is indefinite. The most marked feature was the severity of the toxaemia in relation to the vagueness of the subjective and objective phenomena. The first patient was ill for only four days, the second for eight, the third for six, and the fourth for eighteen days. Enteric bacilli contain a non-specific endotoxin, and, according to Park, Williams, and Krumwiede (1925), the intestinal lesions may be absent and "some of the inflammatory complications which occur in typhoid fever are due to the growth of the bacillus in excessive numbers in unusual places in the body." The occurrence in enteric fever of sudden death from myocarditis and vasomotor paralysis has recently been emphasized by Jacobi (1927).

Generalized abdominal pain was common to all of the cases, and three of the four had vomiting and diarrhoea. In all, at least part of the abdomen was flaccid, and the rigidity, when present, was only slight. The absence of recognizable enlargement of the spleen and of rash was noteworthy. The temperature in all but one of the cases recorded failed to show the classical "step-like" rise, and a low pulse-temperature ratio was not present in any of the cases.

SUMMARY.

1. Four cases of atypical infection with typhoid-paratyphoid bacilli are discussed—3 of *B. paratyphosus* B and

1 of *B. typhosus*. Of these, two presented the clinical picture of cholecystitis—one having gall-stones. The gall-bladder wall of the third case was the only part of the body found to be infected with the enteric organism. The fourth simulated acute appendicitis. All four cases presented profound toxic manifestations, an irregular temperature and abdominal pain. Examination of the abdomen revealed at most only slight rigidity, no rash, and no recognizable enlargement of the spleen.

2. A plea is made for thorough bacteriological examination of cases with vague abdominal symptoms which do not correspond closely to any mild digestive disturbance or acute abdominal condition.

3. In the interests of the community, enteric carriers should be "tracked down," and, when necessary, administrative action should be taken to minimize their danger to those around them, especially by prohibiting their employment in any business where food is handled.

In conclusion, I desire to thank Professor T. J. Mackie for guidance in the course of the investigation; Professor Murray Lyon, Dr. Goodall, and Messrs. Scot-Skirving, Struthers, and W. Q. Wood for the clinical details of the cases; and Professor Lorrain Smith and his staff for facilities for obtaining specimens and permission to publish details of the post-mortem findings.

A REVERSIBLE BED FRAME FOR SPINAL AND OTHER SPECIAL CASES.

BY

ERNEST W. HEY GROVES, F.R.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY OF BRISTOL.

DURING the war one had frequent necessity for a bed which would give ready access to the back or buttocks without moving the patient. Especially did this need arise in cases of spinal injury, in which special daily attention to the skin was required in order to prevent or to treat bedsores. At first we were content with the Pearson's bed, in which the frame is high and the patient is supported on transverse canvas slips any of which can be removed. But this device is very difficult and uncomfortable for nursing, because the nurse has practically to creep under the bed, and even then the back is seen with difficulty. We then had a tubular frame or cage made which was held inside a Pearson's bed frame and was made to turn over. This gave ready access to the back, and proved so useful that when the war was over a special bed was designed which should embody these principles. This has been carried out, and for the expenses of the work I am most grateful to the Association of Surgeons for a grant which they made me for the purpose. The design which was first elaborated was, I think, too complicated, as it included

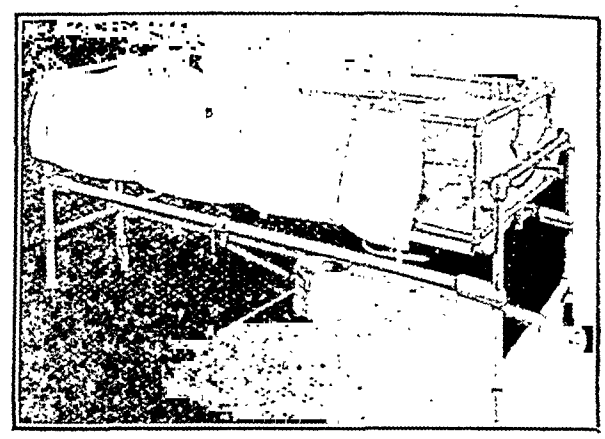

FIG. 1.

a device whereby the cage in which the patient lay could be tilted about a transverse axis, as well as rotated round a longitudinal one. In actual practice we found that the former movement was used so seldom that it was not worth while to have it provided for, as the same effect can be

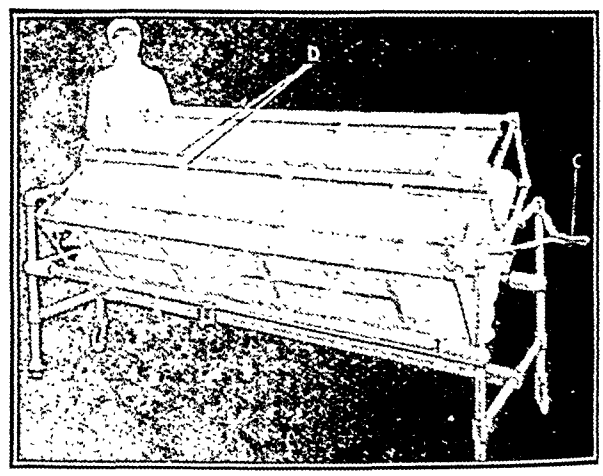

FIG. 2.

attained by lifting the head end of the bed frame and supporting it by two chains placed under the transverse bar.

The model which I am here describing has now been in constant use for the past few years, and it has passed the critical test of those sisters and nurses of the Bristol

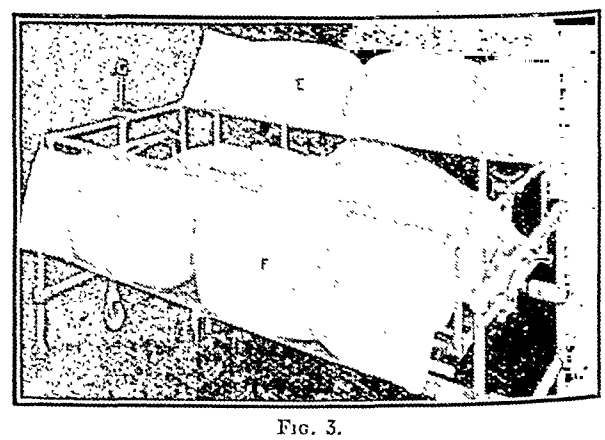

FIG. 3.

General Hospital who have been most enthusiastic in helping me to perfect its details.

The accompanying figures will, I think, serve to illustrate the construction and working of the bed. Fig. 1 shows the patient lying on his back, the head being raised on a pillow. The mattress is made in two longitudinal

halves separated from one another by a space of about 3 inches in their whole length. This gap allows the spine to rest on the split mattress without pressure upon the spinous processes of the vertebrae. In the middle of the bed the gap between the mattresses consists of a hole 8 inches in diameter, into which the special bedpan fits. This hole for the bedpan is suitably protected by rubber sheeting to prevent soiling the mattresses. The bedpan (A) is held by a lever which works in such a way that when pushed into place under the patient's buttocks the bedpan rises close under the hole in the mattress. When the pan has to be emptied the lever is pulled into position, shown in the illustration, and it drops so as to clear the bed frame. The case in which the patient lies is large enough to take a Thomas spinal frame or a hip abduction frame in a moderate degree of abduction. If this is used the lower mattresses would be discarded.

To the sides of the cage are hinged two flaps, on to which are strapped half-mattresses (B). Except when the patient is to be turned over these flaps lie as shown, flat against the sides of the bed cage. When the patient has to be turned over, the pillow is removed from under the head, and one pillow placed in front of and at the sides of his body, so as to pack him tightly in the cage. The flaps are then turned over so as to cover in the front of the patient, and are secured in this position by a catch and screw at the head, and another at the foot of the cage (C in Fig. 3). The front mattresses of the cage, when in position in front of the patient, have a 4-inch gap between them, which gives ample space for the face (D in Fig. 2).

The patient, being now snugly encased between the two sets of mattresses and the side pillows, can be turned over. This is done by releasing the catch (C) at both ends of the bed frame, and Fig. 2 shows the patient in the cage being turned over. When the cage has been reversed by being turned through a half-circle it is fixed in this position by the catch, and the back halves of the cage are open. In Fig. 3 one half (E) is seen being lifted up, and the other (F) has been dropped down by the side of the cage. The patient's back is now fully exposed for the purposes of dressing or attention to the skin of the buttocks.

The cases for which this device has proved to be of the greatest service have been: fractures of the spine, with or without paraplegia and paralysis of the bladder; tuberculous disease of the spine, especially cases in which a bone graft operation has been done; spinal cord tumour with paraplegia, or after a laminectomy; bad cases of fracture of the pelvis; special cases of fracture of both femora; and bad cases of burns involving the back.

The bed has been made for me by Messrs. Nesbitt-Evans and Co. of Wednesbury (Staffs), to whom I am greatly indebted for their trouble in carrying out my design.

THE RELATION OF ORTHODOX RHEUMATIC INFECTION TO MULTIPLE INFECTIVE ARTHRITIS.

BY

VINCENT COATES, *M.C.*, M.A., M.D.CANTAB., M.R.C.P.,

PHYSICIAN, ROYAL MINERAL WATER HOSPITAL, BATH; CARDIAC SPECIALIST, WILTS COUNTY COUNCIL SCHOOL MEDICAL SERVICE.

IT is manifestly impossible from a statistical point of view to assess the relation, if any, between the acute and the more chronic forms of rheumatic disorder unless such terms as "acute rheumatism" and "chronic rheumatism" have a standard significance. As, however, the term "acute rheumatism" in the generally accepted sense means rheumatic fever, and the term "chronic rheumatism" is indiscriminately applied to many dissimilar affections of both muscle and joint, it is proposed in this paper to deal only with orthodox rheumatic infection and with multiple infective arthritis. By the former is meant frank rheumatic fever, and by the latter that type of subacute or chronic arthritis which is non-suppurative and is generally conceived to be due to infection of a non-specific character—in other words, which is not gonorrhoeal, pneumococcal, tuberculous, or syphilitic in nature. "Rheumatoid arthritis," as opposed to osteo-arthritis of the hypertrophic type, and "atrophic arthritis" are other terms for the disorder in question. Any arthritis which can be classified as being due to, or associated with, disordered metabolism, such as climacteric arthritis, is thus excluded from the series under discussion.

The possible relation of orthodox rheumatic infection to multiple infective arthritis was investigated by the following methods.

1. The evidence afforded by the family history of 50 consecutive cases of multiple infective arthritis in regard to orthodox rheumatic infection.

In 16 instances rheumatic fever was known to have occurred in a parent, brother, or sister.

2. The incidence of a clear history of orthodox rheumatic infection in 300 consecutive cases of multiple infective arthritis. By a clear history is meant the patient's positive assertion that rheumatic fever had occurred earlier in life and was not immediately connected with the present disability. This evidence was frequently borne out by the individual's own private practitioner.

Rheumatic fever is believed to have occurred in 14 instances, without, however, the presence of discernible complications of a cardinal nature (for example, carditis or large subcutaneous nodules) at the time of examination. This series does not include 13 additional cases in which rheumatic fever was alleged by the medical practitioner in charge of the case to have immediately preceded the onset of infective arthritis.

3. The occurrence in the aforesaid 300 cases of cardinal signs of orthodox rheumatic infection—namely, cardiac lesions of the orthodox rheumatic type and large subcutaneous nodules of the same histology[1 2] as those which occur in rheumatic fever of childhood. The millet seed granules[3] described by me as occurring in subacute rheumatic infection of childhood and in multiple infective arthritis are not included in this category.

The findings of the cardinal signs of orthodox rheumatic infection in these 300 cases of infective arthritis can be tabulated as follows.

	No Rheumatic Fever.		Rheumatic Fever.	
	No Nodules.	Nodules.	No Nodules	Nodules.
Mitral stenosis	3	2	—	—
Mitral regurgitation	2	—	1	2
Aortic regurgitation (in young subjects with negative W.R.)	2	—	—	—
Nodules	No carditis ... 13		No carditis ... 1	

Conclusions from the Above Data.

1. The incidence of orthodox rheumatic infection in the immediate family history of 50 consecutive cases of multiple infective arthritis is 32 per cent. This is a very high percentage, and accords with the popular conception that "rheumatism" has a familial or hereditary basis.

2. A low estimate of orthodox rheumatic infection in 300 consecutive cases of multiple infective arthritis is nearly 5 per cent. The attack rate of orthodox rheumatic infection among the under 15 population in Norway[4] is given as 0.8 per 1,000, and the highest figures published are from the Royal Naval School at Greenwich[4]—namely, 6 per 1,000. The attack rate was 2 per 1,000 in the 16–24 age period of the Ministry of Health's inquiry[4] into "rheumatism" in insured adults of both sexes.

3. The cardinal signs of orthodox rheumatic infection—namely, carditis and/or subcutaneous nodules—were present in 300 consecutive cases of infective arthritis in the following percentages:

	Per cent.
Cardiac lesions only without a history of rheumatic fever	2.33
Subcutaneous lesions only without a history of rheumatic fever	4.33
Cardiac lesions in the whole series	4.00
Subcutaneous lesions in the whole series	6.00

These cardiac figures are much higher than those given for organic cardiac disease after routine examination of school children[4] in England and Wales, 0.7 per cent.; in Scotland, 0.52 per cent.; and in New York,[5] 1 per cent.

In regard to subcutaneous nodules, Carey Coombs[6] has stated that of the principal phenomena of orthodox rheumatic infection—namely, carditis, polyarthritis, the

subcutaneous node, and chorea—the subcutaneous node is the most "rheumatic" of all. The above figures are therefore, to say the least of it, significant.

SOME EFFECTS OF WARM IMMERSION BATHS UPON THE CIRCULATION.*

BY

GEOFFREY HOLMES, M.B.CANTAB.,
PHYSICIAN, HARROGATE ROYAL BATH HOSPITAL.

SPA physicians are aware that some of their professional brethren are a little sceptical about the efficacy of bath treatments, and it is probably not generally realized what profound effects such a simple procedure as a warm immersion bath may exert on the bodily functions, and especially upon the circulation. Some of these effects can be quite accurately measured. First, and most obvious, is an alteration in the pulse rate. Secondly, variations in blood pressure, both systolic and diastolic. Thirdly, and beyond the scope of ordinary clinical observations, there is a change in the amount of blood flowing from the heart per minute, as well as in the stroke volume or output per beat. Fourthly come various less accurately measurable effects, such as sweating, cutaneous hyperaemia, etc.

The following observations were made during a series of experimental baths taken by three normal subjects with a view to ascertaining the effect of immersion baths on the circulation and to determine whether the consequent variations in pulse rate and pulse pressure were in any close degree correlated with alterations in the heart's output. The effects on the circulation rate will be the subject of a separate paper, but I wish to draw attention to some rather striking effects on pulse rate and blood pressure revealed during these experiments. Typical examples are here given in tabular form.

It is common knowledge that an increase in the body temperature is accompanied by a proportional increase in pulse rate. Our experiments show this effect, but, in addition, two other features appear. (1) When a normal subject is placed in a bath at a temperature of approximately 103° F. there is an immediate increase in the pulse rate long before any significant rise of body temperature occurs. This increase is so sudden that it would appear to be due to some reflex cause, and a subsequent greater rise is superimposed. (2) In certain of the experiments there was definite hyperpnoea and consequent alkalosis (excessive CO_2 elimination). This alkalosis was associated with still further increase in the pulse rate.

It is just thirty years since Edgecombe and Bain[1] published papers on the effect of baths, massage, and exercise on the blood pressure, and these papers are still regarded as classics. They contain no reference to diastolic arterial pressure, but they were written before present-day methods of measuring diastolic blood pressure had been devised. The writers do, however, state the effects on mean arterial pressure, which they define as the reading taken when the indicator of the haemodynamometer gives its maximum excursion. It is probable that this point of maximum excursion would approximate somewhat closely to the diastolic pressure.

Our own observations show that in normal persons entering a bath at 103° F. there is an immediate fall in both systolic and diastolic blood pressure, approximately 10 mm. of mercury in each case. This initial fall would appear to be due to simple hydrostatic causes. When the blood pressure is taken with the subject on a couch the arm is lying by the side. If the arm be elevated to an extent such as occurs when taking the blood pressure of a patient immersed in a bath, a similar fall is observed. Subsequent to these immediate changes the systolic pressure may show a slight rise, which in none of our experiments exceeded 16 mm. of mercury, but was usually rather less. The most striking feature with regard to blood pressure was a marked fall in diastolic pressure, together with an alteration from the normal characters of the Korotkow sounds—that is, the sounds heard in the artery during decompression when determining blood pressure by the auscultatory method.

Wiggers[2] describes five phases in the Korotkow sounds:

"*First phase:* The sudden appearance of a clear sound, lasting for a fall of approximately 14 mm. of mercury. This has already been described as a criterion of systolic pressure.

"*Second phase:* The acquisition of a murmurish character, lasting while the pressure falls approximately 20 mm. of mercury more. It is attributed to the stenosis of the vessel produced under the cuff at this stage.

"*Third phase:* The replacement of the murmur by a sound becoming progressively louder and lasting during the next 25 mm. of pressure fall.

"*Fourth phase:* The muffling of the sounds, lasting while the pressure falls 5 to 6 mm. more. The cause of this muffling has been variously interpreted as due: (*a*) to the absence of diastolic collapse; (*b*) to the slowing of the stream under the cuff; (*c*) to the decreased resonance in the deflated cuff; (*d*) to a lack of flattening of the arterial wall.

"*Fifth phase:* The disappearance of all sound."

The pressure in the cuff at the commencement of the fourth phase is generally accepted as being the diastolic pressure. We found that although normally at rest the transition from the third to the fourth phase was well defined, and gave a sharp reading of diastolic pressure, after a short time in a bath at 103° F. this was no longer so. Almost immediately the sounds during the third phase, instead of becoming progressively louder throughout the whole of the phase, became at first louder and then gradually softer, and during this period of diminuendo tailed off almost imperceptibly into the fourth phase. Hence it was not possible to recognize the usual clearly defined criterion of diastolic pressure. In addition, the fourth phase became prolonged, and, not infrequently, after the subject had been in the bath for thirty minutes or longer, the fourth phase was found to continue right down to zero pressure—that is to say, the fifth phase was absent altogether.

In column three of the table the left-hand figure is, so far as could be ascertained, the transition from third to fourth phase. The right-hand figure, where only two are given, is the pressure at the end of the fourth phase—that is, disappearance of all sounds. Where this figure is zero it indicates that sounds were still present in the artery when the sphygmomanometer cuff was completely deflated. Where three figures are given, the front two show pressures at which clearly defined softening or muffling of the sounds occurred. So far we are unable to interpret these points with reference to Wiggers's phases, but it seems at least possible that in the later stages of a hot immersion bath the diastolic pressure falls very near to zero. These changes—namely, the fall in diastolic pressure and alteration of the Korotkow sounds—closely resemble those observed in severe cases of Graves's disease (hyperplastic exophthalmic goitre), and possibly also in cases of aortic incompetence and severe anaemias.

The significance of some of these observations is as yet obscure, but one point of interest may be briefly mentioned. It has generally been considered that an increase in pulse pressure associated with an increase in the pulse rate is indicative of an increase in the circulation rate. This has been shown to occur in exophthalmic goitre. Our observations on the circulation rate in baths have shown that, as a rule, no significant increase in circulation rate occurs even though both pulse rate and pulse pressure are increased. Indeed, in certain experiments the circulation rate under these conditions has been found to be actually lessened.

In the present communication it is impossible to give all the evidence in detail, but the most reasonable interpretation of such changes as we have observed and measured would be that there is constriction of the arteries and arterioles, together with a dilatation of the capillaries. This dilatation gives rise to diminished peripheral resistance, as well as a certain amount of peripheral stasis.

* A preliminary communication summarizing an address to the Yorkshire Branch of the British Medical Association at Harrogate on October 11th, 1929, and based on observations made in collaboration with Professor Whitridge Davies and a number of the senior students from the Leeds Medical School. The work was carried out at the Royal Baths and the Royal Bath Hospital, Harrogate.

The presence of peripheral stasis was further confirmed by the appearance in some experiments of a slight though quite appreciable cyanosis of the limbs. The normal, or sometimes diminished, general circulation rate, together with the increase in pulse rate, indicated an appreciable, and sometimes considerable, diminution in the output of the heart per beat.

The above figures are those obtained during two of the fourteen experimental baths on which the conclusions in the paper are based.

SUMMARY.

The following are the principal circulation effects noted during immersion baths at 103° F. in normal subjects:

1. Rise in pulse rate.
2. Maintenance, or increase, of systolic pressure, allowing for slight alterations in position of arm.
3. Fall in diastolic pressure.
4. Changes in pressure levels at which modifications of the Korotkow sounds occur.
5. Persistence of these sounds down to 0 mm. of mercury in certain readings.
6. Prompt return towards normal when the subject is cooled down on completion of bath.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FOREIGN BODY IN RIGHT BRONCHUS OF A BABY.

THE following case, in which a flower-spike of grass passed through the upper air passages and lung tissue to present beneath the chest wall, is of interest both from the mechanical aspect and on account of the fact that so little disturbance was caused.

The patient, a baby of 9 months, was admitted to the St. Albans and Mid Herts Hospital for observation on August 30th last. For two weeks the child had been fretful, with screaming attacks and occasional cough. On admission the temperature was 100°, pulse 120, and respirations 36. The general condition was fairly good, but screaming fits persisted. No abnormal physical signs could be detected except an impaired note over a limited area below the angle of the right scapula; adventitious sounds were absent and breath sounds were not appreciably altered. The temperature settled on the following day and screaming ceased. No further symptoms developed except an expiratory grunt, noticed especially at night. Chest signs remained unchanged. The child was discharged six days later apparently quite well.

On September 11th the mother noticed a "swelling on the back," and called in Dr. Ronald Wilson. He suspected a foreign body, and, on further questioning, obtained a history of a choking fit on August 12th—two and a half weeks before the first admission to hospital.

On readmission to hospital, on September 12th, the temperature was 99.8°, the pulse 136, and the respirations 34. The general condition remained fairly good. There was a tender swelling, two inches in diameter, extending downwards from the angle of the right scapula. It was fixed to the deep structures and had a small central red area but no fluctuation. Breath sounds were harsh in the neighbourhood of the swelling, but unchanged over the rest of the lung field.

On September 13th a radiogram showed thickening of the right ninth rib under the site of the swelling, with a cup-shaped area of rarefaction on its inferior margin and a well-defined opacity of lung field locally.

On September 14th, under a general anaesthetic, the tumour was aspirated, but no pus was found; incision revealed an inflammatory oedematous condition of the thoracic parietes, and no collection of pus. In the base of the wound a foreign body was exposed. This was withdrawn and found to be a flowering head of "wall barley," 1½ inches long (see photograph) with stalk end projecting outwards, and of slightly offensive odour. On passing a probe a sinus was found leading direct up into the right bronchus, reflex coughing being produced thereby. The wound was closed without drainage. A small superficial collection of pus formed, but rapidly cleared up, and the child had no further pyrexias or respiratory symptoms.

On September 23rd the patient was discharged with the wound completely healed. There was still a slight impairment of note, but no swelling, and breath sounds were good over the whole lung.

I am indebted to Mr. D. Morgan Jones, surgeon in charge of the case, for permission to publish this note.

V. SMALLPEICE, M.B., B.S.,
House-Surgeon, St. Albans and Mid Herts Hospital.

CHRONIC RHINITIS IN CHILDREN.

A FACTOR to be reckoned with in the treatment of chronic rhinitis in children is the large area of nasal mucous membrane involved. The area of the septum and lateral walls (not including any sinuses) in a small female subject in the dissecting-rooms of the Sheffield University was 225 square centimetres. As this mucous membrane is lying over immovable bone the removal of any excess of mucus must be dependent on (1) transmission along the surface by the action of the cilia, and (2) the expulsion of mucus by means of air currents.

By the reflex act of sneezing, which is an explosive form of expiration, an extra amount of secretion is poured out, which acts as a powerful cleansing force, loosening any debris collected there. If the sneeze is at once followed by a voluntary expiration through the nose (keeping the mouth shut and bending the head downwards) the old debris can be blown out of the nose. If the sneeze, or sudden involuntary expiration, is followed up by a short,

quick inspiration, as in sniffing, these particles are drawn up the olfactory cleft into its absorptive columnar epithelium, or else fall back on the nasopharynx, with its absorptive lymphoid tissue; some are finally swallowed and absorbed by the stomach, so that in sniffing there is a constant reinfection taking place.

In treating chronic rhinitis children must be trained as follows.

1. They must be taught how to blow the nose. Various methods are adopted with children of different ages.

2. They must be taught the act of sneezing. The frontal reflex is quite successful in some cases, and sneezing can be evoked by tickling the face, in exactly the same manner as is done by the Maories in their baptismal ceremony. When the priest recites the names of the baby's ancestors he tickles its face with a twig dipped in water, and when the baby sneezes it is supposed to have pronounced its own name. The easiest and quickest sternutatory I have found to be exsiccated sodium carbonate. By using a little tact and camouflage children can be made to sneeze without knowing about it, no matter how young or nervous they may be; as sneezing is regarded as a laughing matter by young children they do not object.

3. They must also be taught to blow the nose after the sneeze so as to get rid of the old debris.

4. They must never be allowed to sniff. This last point in the training involves the co-operation of the mother, who has to provide the child with a handkerchief and an easily accessible pocket.

This is the method advocated by Dr. Octavia Lewin; I have carried it out on 200 volunteers with great success during the last five years, the success being gauged by the continuous attendance at school of the children so treated.

There are many primitive ideas regarding sneezing which must be overcome; these ideas have been handed down through the ages, and are, perhaps, the unconscious basis of objections to sneezing in some cases. For instance, among the primitive islanders in the Pacific the Dyak mothers in Borneo, when their babies sneeze, call out, 'Soul, come back"; this idea that the soul lives in the nose, and can be lost by sneezing, is mentioned in Hindu legends, and is also among the beliefs of Red Indians.

LUCY NAISH, M.B.Lond.,
Lecturer in Osteology, University of Sheffield.

Reports of Societies.

ETIOLOGY AND TREATMENT OF RHEUMATOID CONDITIONS.

AT a *meeting of the Devon* and Exeter Medico-Chirurgical Society on December 19th, 1929, the president, Dr. B. COHEN, read a paper entitled "Rheumatoid conditions."

Dr. Cohen said that, although he would deal chiefly with rheumatoid arthritis and osteo-arthritis, much would apply equally to conditions such as myositis, fibrositis, "lumbago," and the various ill-determined affections classified as neuritis, for a large percentage of sufferers gave a history of vague rheumatoid conditions for several years prior to the definite establishment of arthritis, and it was during this incipient period that happy results might be achieved by treatment. The disease could be traced back to the Mesozoic period, long before the advent of man. For example, arthritic changes had been demonstrated in the cervical extremity of the skeleton of the giant Iguanodon, and, later, similar affections had been found in the cave bear and the sabre-toothed tiger; finally, remains of men in the Stone Age similarly affected had been discovered. It was the outstanding disease of the ancient Egyptians, and the importance attached to hydrotherapeutic establishments by the Greeks and Romans told its own tale. Spas in Europe, such as Aix-les-Bains, had been frequented continuously for the last 2,000 years. Dr. Cohen then touched upon the economic effect of rheumatoid disease on the country to-day, with an annual cost of £2,000,000 in sick benefit and loss of 3,000,000 weeks of work. The most common age incidence was after 40, women being more susceptible than men. It was generally held that infection arose from some primary focus elsewhere in the body—such as the teeth, tonsils, antra, and the genito-urinary tract. Pemberton had ranked exposure as a predisposing cause in 58 per cent., but his figures seem to have been based on army cases, and the higher occurrence in women in civil life needed explanation. The disease was more prevalent in cold damp places, and there was reason to believe that the physiology of muscle became consequently predisposed to rheumatoid affections. Omitting reference deliberately to the arthritis of the acute infectious diseases, the speaker defined two groups—the atrophic and the hypertrophic—or, as generally known, rheumatoid arthritis and osteo-arthritis respectively. The atrophic type was associated with asthenia and a slight build, the patient being below or about the age of 40; the hypertrophic type occurred at a more advanced age in a person of robust build and of fit appearance. In the atrophic form the disease was multi-articular with effusion into the joints; atrophic changes affected the skin and muscles, and finally ankylosis might ensue. The hypertrophic disease was frequently mono-articular, and deformities were due to osteophytic outgrowths and not to ankylosis. Evidence in respect of infection from remote foci had been secured by the removal of cartilage from the joints. The fact that protein shock therapy had given benefit in some cases supported the theory that anaphylaxis might have some bearing on arthritis, and Dr. Cohen reported a case of asthma, urticaria, and arthritis occurring in the same patient, one affection improving temporarily while the other predominated. There was little proof that acid foods or the accumulation of lactic acid were agents in producing arthritis, but more could be adduced for the lowering of the basal metabolism which was noted in 20 to 30 per cent. of the cases, and the occasionally favourable effect of thyroid therapy. B. Ray had hypothecated a rheumatic substrate operative throughout the body, explicable by the unbalanced state of the autonomic nervous system, septic foci being only one link in a tortuous chain. This theory seemed to find support in the resemblance of the joints of rheumatoid arthritis to those in tabes and syringomyelia.

Pemberton had discovered a delay in the fall of the blood sugar curve in arthritis in 70 per cent. of the cases, with a return to normal after the removal of a septic focus. So consistently did this appear that, if a curve did not so respond to the removal of a focus, Pemberton rejected that focus as being a cause of the arthritis; he had also demonstrated slowing of the capillary circulation, which he thought was the cause of the delayed sugar fall. He had been induced to perform these experiments by the fact that his arthritic patients improved when carbohydrates were cut out of their diet. Mutch, working in this country, had found the predominant organism in the intestinal tract to be *Streptococcus longus*, which was strongly glycophylic. These organisms lived only in the intestinal canal; in the presence of stasis and sugar they destroyed *B. coli* and retained their infective properties. Dr. Cohen pointed out that it was interesting that these two workers, one through biochemistry, and the other through bacteriology, had come to the same practical conclusion that carbohydrates in the diet should be reduced. He reconciled the two views by suggesting a mild infection of the pancreas. As regards the mechanics of intestinal stasis, the fault might lie on the proximal side of the ileo-caecal valve, and, although not recoverable from the faeces, the intestinal tract might be teeming with streptococci. In one of Mutch's cases the glycophylic organism found in an appendix abscess had been recovered from the empyema which developed as a sequel.

Passing on to the treatment of arthritis, Dr. Cohen emphasized the importance of determining the cause and then concentrating against it. When the origin was microbic the greatest care should be taken to isolate the organism at the time of removal of the focus; he emphasized the need for cultivating direct from the apex of an extracted tooth, avoiding all possibility of contamination, and for smearing the culture direct from the centre of the removed tonsil. Other possible sources of infection were the cervix, the prostate, and the gall-bladder. Dr. Cohen maintained that when organisms were present in the urine they were evidence of intestinal infection. He himself had never seen bacilluria unassociated with intestinal

stasis, and he regarded the kidney as merely acting as a filter in these cases. As regards removal of the foci, he called attention to the danger of the wholesale extraction of teeth under anaesthesia, and expressed the opinion that the smaller the tonsil was the more deadly it often proved as a nidus of infection. Having dealt with the possible focus, treatment, with vaccines or otherwise, followed. The course of injections should be undertaken and watched by the same man. Where the infection was derived from the mouth or throat Dr. Cohen started with a very small dose and increased gradually, thus: ¼, ½, ¾, 1, 1½, 2; whereas with intestinal vaccines he generally used the "double-up" method—1, 2, 4, 8, 15, 30, 60, 125, 250, 500, 1,000. If no reaction resulted from twelve doses at weekly intervals he relinquished the treatment, whereas, on the contrary, a mild reaction led him to repeat the dose responsible at intervals of a fortnight over a period of months. Dieting was most important in treatment, but preliminary bacteriological and radiological investigations of the intestinal tract were essential. Nowadays the old uric acid theories and consequent restriction of meat held no sway; it was found that in 70 per cent. of the cases the carbohydrates were at fault. The main point in diet was to reduce the load at the expense of the carbohydrates, an easier task with the hypertrophic cases than with the atrophic and asthenic; liver treatment proved useful where anaemia was a symptom with the latter class. Plombières treatment played an important part, but should be relegated to an expert guided by radiological findings. Potassium permanganate, both by injection and by the mouth, had proved a useful adjunct; in connexion with this Dr. Cohen deplored the multiplication of "colon filling stations" about the country. Aperients could not be omitted in all cases, but Dr. Cohen advocated the repetition of small doses of the less drastic aperients rather than brisk purgation by a single dose. Massage was of the greatest value, in combination with local heat, as an agent in the prevention or delay of muscle atrophy; in the improvement of the general metabolism; and in respect of mechanical influence on the circulation. Internally, thyroid and iodine were invaluable where there was evidence of thyroid deficiency. Nitrites were promising in that they had a favourable influence upon the blood sugar curve. Deep x-ray therapy had been found to have some good influence, but adverse results did occur, and especially in acute cases, and here Dr. Cohen gave a special warning in respect of vaccines also, and of any form of heat treatment away from the home. In all cases the personal equation entered largely into the choice of treatment, and the confidence of the patient in any one form would largely make for its success.

In conclusion, Dr. Cohen mentioned the influence of trauma in the production of arthritis, and cited a case of fracture in the region of the ankle-joint under his care many years ago. The man had pyorrhoea, and developed an arthritis of the ankle during the time he was under treatment for the fracture. It was therefore important, he added, to ensure against the possibility of septic foci, either in the mouth, throat, or intestinal tract, in all cases of trauma, and more especially if the accident occurred in a person about the age of 40. The case was the same with the patient aged 40 or thereabouts who was becoming "rheumatic," and for whom early investigation and treatment was of paramount importance.

Dr. R. V. SOLLY, commenting on the blood sugar curves shown by Dr. Cohen, remarked that one was rather high and the others low after the removal of the focus of infection: glycosuria might have been suspected in the first one. He had noted uncertain results with the vaccine treatment of arthritis, and benefit was often difficult to gauge owing to vaccines being given in combination with other forms of treatment. Mr. R. WAYLAND SMITH agreed as to the importance of guarding against oral sepsis in all cases of fracture, and mentioned cases from the United States where arthritis had cleared up after amputation of the cervix uteri. He asked if Dr. Cohen had met with success from using ultra-violet rays. Mr. R. WORTHINGTON could not mention any one case where he had cured arthritis by removal of the tonsils, but he had seen good results when operating in early cases of fibrositis, where repeated sore throats gave evidence of infected tonsils. When pronounced bony changes had occurred in the joints one could not hope for success. The speaker thought it preferable to obtain the organism from the intestinal tract rather than by section of the tonsil, and he attacked the tendency of too radical dental extraction. Dr. R. MICHELMORE commented on the difficulties which beset a panel doctor in providing the special treatment appropriate to these cases.

Dr. COHEN replied that although he had used ultra-violet rays without benefit he would try them again in cases of lowered metabolism. He had not treated any cases with intra-articular injections of oil, but he could quote improvement after saline injections under the strictest precautions. Rheumatism was a very big problem which the country would have to face in the immediate future, just as it had dealt, and was still dealing, with tuberculosis.

CHILD PSYCHOLOGY.

AT University College, London, on January 1st, under the auspices of the Child Study Society, Dr. H. CRICHTON-MILLER addressed a large gathering of teachers on the study of the child.

The lecturer's remarks, notwithstanding the title of his subject, pointed rather to the need for the study of the adult and the correction of some obvious adult faults in relation to the child. Many of the adult complainings with regard to children—their noisiness, their unwashedness, their peccadillos—were really, in Dr. Crichton-Miller's view, part of a campaign of adult sophistication against childish instinctive reactions. He reminded his audience that a child given to stealing sugar might be one of those unfortunate persons who suffer from sugar starvation, and the mere rebuke of the habit, without an understanding of the underlying cause, would not carry very far. It was impossible to get down to the actual behaviour of the child while it was under the shadow of the adult. There were parents who were always eclipsing the child, who seemed incapable of coexisting with the child unless they cast around it a shadow. He believed that in America, in connexion with some child clinics, a system had been devised of observing the child when it was unconscious of adult proximity, periscopes and microphones being employed; but short of this, there were some gifted people who had a marvellous way of attenuating their shadow until it became no more than that of a telephone pole, while that of others spread out like a beech tree. One condition on which Dr. Crichton-Miller laid stress was the need for neutrality in the child's environment. Many children suffered, he said, from a bias in their environment; they were unlike other children with whom they were perforce associated, and the difference led to unjust estimations, expectations, or depreciations in the mind of others. An extreme example would be one African child in a class of European children. Every departure from neutrality in environment meant some deviation or deflection of the child's purpose in life. Proceeding to speak of the goal of the child, which, he said, was adaptation (a thing of much broader significance than the choice of a business career), Dr. Crichton-Miller said that the child must be able to adapt itself to both success and failure, to prosperity and adversity. He sometimes wondered when he saw some of these dreadfully protected children, these poor little victims of a purblind parental devotion, who were never allowed to have a cold or a fall, or to encounter any form of adverse circumstance, such as the possibility of being physically overcome by another child, how they were ever going to meet the slings and arrows of outrageous fortune in after-life. When was it too early for children to begin to take the rough with the smooth? That was not a problem in child study, but in adult study. The child who lived the too protected life was hampered from the first in its capacity for adaptation. Dr. Crichton-Miller went on to speak of some behaviours of little children which might appear on the surface to be ordinary instinctive reactions of practically no significance, but which eventually had a profound motivation. The ignored, the undervalued, the unwanted child began a series of motivated reactions which were intended to acquire value for itself. Such a child, after having had an attack of

affective reactions to the experiences of life. Highly intense life impulses, together with strong inhibitions, great critical intelligence and power of sublimation, a weak projective capacity balanced by a strong trend towards co-ordination—such are the factors discovered by the author in the psychic structure of these philosophers. In philosophic activity it is possible to discover biological values—it serves as a substitute for practical action in the discharge of excess impulse energies; it creates, in the place of harsh and intractable and therefore unsatisfying reality, a painless and therefore satisfying world; and it leads by means of a detour to the real satisfaction of powerful interests. The thesis of the writer would seem to find points of contact with the generalization of Adler to the effect that an inferiority may, according to the general conditions obtaining, eventuate in three different modes of reaction—degeneracy, neurosis, genius.

THE BLOOD PICTURE.

PROFESSOR VICTOR SCHILLING'S *Das Blutbild und seine Klinische Verwertung*,[5] first published in 1912, is presumably a textbook well known to German haematologists. The present, so-styled, seventh-eighth edition is an American version of this work. Apparently the author's chief object is to advocate the use of Schilling's "haemogram" in preference to the more elaborated nuclear classification of Arneth. While we accept the more practical convenience of the "haemogram," we consider the claims to diagnostic importance of both these schemes are exaggerated. The introduction of yet another haematological method, for which Professor Schilling has devised the ingenious name "guttadiaphot," is perhaps premature; the author admits that "before we can establish the usefulness of the method and draw proper conclusions from it by scientific biologic study many tests must be made." Professor Schilling is unfortunate in his translator. We do not share the optimistic feeling he expresses in his preface that "when the great group of American laboratory investigators and clinicians have had time and opportunity to learn these methods they will find here a great help in everyday practice." A guide-book so ill arranged and so badly expressed can surely only add to their burden. We read on page 63, dealing with the sedimentation test of blood corpuscles: "Guided by Hoeber's work . . . it was thought possible to recognize the accumulation of albuminous decomposition products in plasma as the cause of the 'suspension instability' (Fahraeus). The 'globulin fraction' of the serum (fibrinogen + globulin) increases as compared to the serum albumin. In this way, according to Hoeber's theory, the negative charge of the erythrocytes is neutralized by increasing through *absorption* at their surface of dispersed, positive albuminous particles." What will clinicians make of this? Again, dealing with the same subject, on page 65: "*Physiologic acceleration* to a slight degree is found in children and women as compared to men, during menstrual periods, and sometimes in asthenics permanently."

PRACTICAL THERAPEUTICS.

Modern Methods of Treatment,[6] by Professor L. CLENDENING of the University of Kansas, is a book that has evidently supplied a popular need, for a third edition has appeared within a year of the second. There are no changes of importance, but paragraphs have been added describing certain new drugs such as synthalin, and the articles on quinidine, liver extract in anaemia, and the use of iodine in goitre have been revised. The principal virtue of the volume is that it covers every department of medical therapeutics, and drug treatment is described in relation to other forms of therapy. The only disadvantage of treating a wide field of knowledge in a single volume is that it is difficult for the author to avoid inaccuracies in those subjects with which he is least acquainted. The book would have been improved by a more careful revision from the biochemical aspect. For example, Kendall's formula for thyroxine is given, although Harington's formula is now generally accepted. Similarly, nothing is said about the international unit for measuring the dose of pituitary extract. These are, however, minor points, and the outstanding features of the book are that it is eminently readable, and it gives a clear and detailed account of how a patient can be treated. The author says: "My aim has been to describe each method of procedure so clearly and minutely that a person who has never seen it performed could do it from the description." The author has undoubtedly accomplished his aim, and the book is one which deserves its evident success.

[6] *Modern Methods of Treatment.* By Logan Clendening, M.D. Third edition. London: H. Kimpton. 1929. (Sup. roy. 8vo, pp. 813; 95 figures. 45s. net.)

AN OBSERVER IN AMERICA.

AMONG several unusually interesting and informative books which have recently been written about the United States of America, one by Professor RICHARD J. A. BERRY, entitled *Through the States with a Seeing Eye*,[7] certainly is worthy of a place. The adjective which best describes it is, perhaps, "vivid." Professor Berry could never be commonplace: he is always keen, observant, and shrewd in his judgements. These qualities are as evident in these talks as in his other writings. Indeed, the chapters of his book are a series of "talks" which he was asked to broadcast from Melbourne. They are now "proffered in book form, exactly as delivered over the air," and they have been described by Sir James Elder, formerly Australian Trade Commissioner in New York, as "correct, informative, bright, breezy, and humorous." The tour which they in some sort narrate, and out of which the observations they contain have arisen, was undertaken for professional purposes and under the auspices of the Rockefeller Foundation of New York. The places described are New York itself, Boston, Baltimore, Washington, Nashville, St. Louis, Chicago, Detroit, and Ann Arbor; and among the general subjects dealt with are American railroads, American hotels, the American dialect, prohibition, the negro question, and the Ku-Klux-Klan. It would be easy to pick for quotation paragraphs on each of these subjects, and in respect of each of these towns, which would illustrate attractively the qualities of Professor Berry's work as characterized above; but the book—not a long one—should be read as a whole. It is only thus that its humour, its wisdom, and its essential fairness can be fully or properly appreciated. If the last chapter, "And what shall the verdict be?" does not result in an altogether flattering conclusion it is a kindly one, recognizing the "strength and weakness, the achievements and manifold follies, the genius, and the obsessions of these myriads of peoples of the United States of America." The volume is illustrated by many interesting original photographs. It can be commended as giving, of its kind and compass, one of the best and most living pictures of "the life, manners, customs, habits, and complexities of a great nation, great in its strength and in its human weaknesses."

NOTES ON BOOKS.

THE fourth volume of the fifth edition of Professor CARL OPPENHEIMER'S encyclopaedic work on ferments and their action[8] is devoted to the technology of ferments. The first half of the book (357 pages), which is written by DR. ALBERT HESSE, deals with the use of ferments in brewing, while the second half (370 pages), to which several authors contribute, treats of such subjects as the preparation of rennin, the tanning of leather, the preparation of medicinal ferments, and the baking of bread. The volume is intended for reference purposes, and descriptions are given of the more important patents that cover fermentation processes. Drawings and photographs are also given of apparatus for carrying through ferment processes on the commercial scale.

[7] *Through the States with a Seeing Eye.* By Richard J. A. Berry, M.D., F.R.C.S. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1930. (Cr. 8vo; pp. 200; illustrated. 5s. net.)

[8] *Die Fermente und ihre Wirkung.* Von Professor Carl Oppenheimer. Die Technologie der Fermente, Band iv, Fünfte, völlig neu bearbeitete Auflage. Leipzig: G. Thieme. 1929. (7½ × 10½, pp. xvi + 727; 107 figures. M.75.)

The necessity for normal standards is well illustrated in all radiographic work, and Dr. OSKAR KIRSCH has performed a valu[illegible]graph on the principles of the [illegible] of the heart and thorax in c[illegible] of measurements of 142 children of all ages, presenting in tables the age, height, and weight, as well as the measurements obtained, in an orthodiagram. He then analyses these results at length, and in various ways seeks to find some mathematical relationship between other measurements of the body and those of the heart. The last section of the book is concerned with this schematic representation of the size of the intrathoracic organs, and the subject is discussed fully, with a large bibliography. Twelve orthodiagrams are included to illustrate various types of children and the size of their hearts.

The second number of the proceedings of the German Society for the Study of the Circulation[10] contains discussions on a variety of subjects, and in this respect it resembles closely the first number, which was reviewed in the *British Medical Journal* of January 5th, 1929. The most attractive contributions are those on oedema, for they take the form of essays and penetrate deeply into the problem.

Dr. DIETEL'S inaugural address on enuresis[11] gives a full and well-written summary of the many varieties of causes to which this distressing complaint may be due in different cases, and adds a practical account of the various forms of treatment prescribed for it or found useful in its management. The book is an encouraging one to read, as the author holds that, in a large percentage of cases, it may be cured, particularly if its etiology can be set on a sound basis in any special instance. He gives a full account of Cathelin's method of treatment by epidural injections in the sacral region, using normal saline solution to the amount of 5 or 10 c.cm.: he himself has treated 32 cases by this method, curing 17 and leaving only 4 unimproved. The book should be read by all medical men who have cases of enuresis to deal with.

The Local Government (Scotland) Act, 1929,[12] by Mr. W. E. WHYTE, solicitor, is a handbook designed for the use of those concerned with the administration of this Act. It deals fully with the administrative and financial changes brought about by the Act, first, by a narrative outline of the provisions, and, secondly, by a reprint of the Act, with full notes and references on each section. Appendices and an ample index complete a very useful and authoritative guide to the complexities of the new measure.

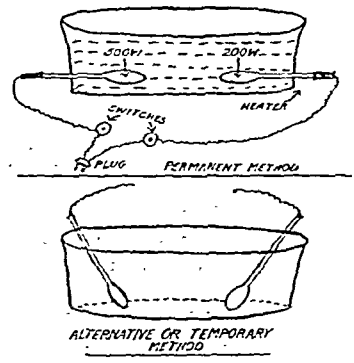
PREPARATIONS AND APPLIANCES.

A RADIUM NEEDLE INTRODUCER.

DR. D. A. CROW (Hove) writes: Messrs. Allen and Hanburys Ltd. have constructed a radium needle introducer to my design, and improved on details which I suggested. Its scope is somewhat limited to the application of radium to growths in



the less accessible parts of the pharynx (epiglottis, pyriform fossae), and possibly the uterus and rectum. Radium is conveniently introduced into the tongue or tonsil region by means of a more simple introducer; lower down, in the œsophagus itself, some form of intubation seems the most appropriate method. In the middle region of the lower pharynx, however, I have felt the need of an instrument which can be used through a direct laryngoscope, and the one suggested has proved slender enough for this purpose; moreover, it affords a very accurate aim.

The silk-threaded needle lies in a groove, A, in the shaft, B. It is held down by a spring, D, and propelled by a movable bar, C, through a countersunk opening in the square-ended, rough-surfaced foot-piece, E, which is held firmly on to the surface of the growth, all movements being slow and gentle to avoid damage to the silk thread.

The same firm has also made at my suggestion a chromium-plated head mirror, which has the advantage over the silvered glass mirror of being light and non-breakable.

A SIMPLE AND INEXPENSIVE ELECTRIC STERILIZER.

DR. E. M. R. FRAZER (Burton-on-Trent) writes: Electric sterilizers are expensive to buy, and I have devised one from the following simple and cheap instrument, using one fish-kettle type sterilizer, about 16 in. by 6 in. by 3½ in., and

costing about 12s. 6d. to 15s. Two electric "immersion" heaters of suitable voltage are employed, one of 500 watts loading, the other 200 watts; they cost about 4s. 9d. each. These heaters are similar in shape and size to an ordinary tablespoon. An electrician will solder a heater into each end of the sterilizer, incorporating a switch in each lead, and also a suitable plug or adapter for connexion to supply.

The vessel is filled with water and both heaters are switched *on*; the water boils in about seven minutes. The 500-watt heater is then switched off, the low-power one being sufficient *to keep the water boiling.*

The advantages are obvious—namely, the low initial cost (about 28s.); very rapid boiling; and the low consumption of current. One precaution is necessary: the heaters must be under water when in use, before the current is switched on, and the vessel must never be allowed to boil dry. Soldering is not necessary, since if it is desired to use the heaters for any other vessel they may simply be placed in the sterilizer before use. The sketches make the idea clear.

HIGH-TENSION TRANSFORMERS FOR X-RAY WORK.

We have often commented on the amount of well-condensed and useful information given in the catalogues of reputable manufacturers. This is true of the latest catalogue to reach us from Watson and Sons (Electro-Medical) Limited, of Sunic House, Parker Street, Kingsway, London. The body of the catalogue consists of an illustrated description of the various types of high-tension transformers built by this firm, but it is prefaced by an admirable account of the principle underlying such transformers and their construction and control. High-tension transformers, which convert the supply current received from the mains at a pressure of 100–250 volts to a current at a pressure of the order of 50,000 to 200,000 volts required to operate the *x*-ray tube, have contributed greatly to simplification of *x*-ray work by eliminating the vagaries and uncertainties of the induction coil. The methods of rectification, testing, and rating are set out, as well as the forms of rating prescribed in the British standard specification introduced by the British Engineering Standards Association, to which the transformers listed in this catalogue conform.

SOME PALATABLE PREPARATIONS.

We have received from Messrs. Wyleys Limited (*Coventry*) a number of recent preparations. Elixir ephedrine co. is a palatable liquid preparation containing 1/4 grain ephedrine per fluid drachm, and also contains various tinctures. Aromatic cascara is a preparation of cascara sagrada almost devoid of bitterness. Elixir bromo-valerian co. is a palatable preparation containing bromides and various tinctures. The same firm also sends samples of ruscol, an ointment containing an organic compound of bismuth and birch tar, which is recommended for a variety of skin diseases.

GLYCERIN OF THYMOL PASTILLES.

Compound glycerin of thymol pastilles (Messrs. Boots) are a new variety of antiseptic pastille. Their action is chiefly due to the presence of a powerful new antiseptic (amyl-meta-cresol), which has a Rideal-Walker coefficient of 250. Each pastille contains the equivalent of 2½ grains of pure phenol. In spite of this powerful antiseptic content the pastilles have a pleasant flavour and are agreeable to use.

DEVELOPMENTAL HISTORY OF THE PRIMATES.

PROFESSOR J. P. HILL'S CROONIAN LECTURE.

THE following is an abstract of the Croonian Lecture for 1929, on the developmental history of the primates, delivered before the Royal Society by Professor J. P. Hill, F.R.S.

Starting with the relatively simple developmental conditions met with in the Lemuroidea, Professor Hill considered the question of how the much more specialized and modified developmental relations found in the higher primates might be supposed to have arisen as the result of adaptive specialization, involving more especially acceleration and abbreviation in the developmental processes. A broad survey of the early development and placentation in representatives of the chief divisions of the order had led to the recognition of four main stages in its evolutionary history—lemuroid, tarsioid, pithecoid, and anthropoid.

The existing lemurs, said Professor Hill, were regarded, from the developmental point of view, as remnants of that basal lemurine stock from which the higher primates took their origin. In their development they exhibited a combination of primitive features with others which were certainly advanced, and which foreshadowed conditions characteristic of the higher types. Primitive features were evinced in the constitution of the blastocyst and its central type of development, in the disappearance of the covering trophoblast and consequent exposure of the embryonal ectoderm, in the origin and mode of spreading of the mesoderm, in the formation of amnion by folds, and in the development of the allantois as a free vesicle. Among the advanced features might be included the relatively early establishment of a complete chorion and its direct and complete vascularization by the ingrowth into it of the allantoic vessels and the reduction of the yolk-sac and its vessels. Their placentation was regarded as genuinely primitive, and the lecturer considered the manner in which the more specialized haemochorial type of the higher primates might have been substituted for it.

In the tarsioid stage, as exemplified by the existing tarsius, was to be observed the retention of certain lowly features characteristic of the lemuroids—for example, the exposure of the embryonal ectoderm and the development of the amnion by fold formation. At this stage certain developmental tendencies could be discerned which were already foreshadowed in the lemuroids—namely, the still more precocious differentiation of the extra-embryonal mesoderm, coelom, and chorion, and the replacement of the vesicular allantois by the almost solid connecting stalk, all of them features in which tarsius anticipates the pithecoids. Also present were certain definite advances on the lemuroid, in particular the acquisition by an early blastocyst of a direct attachment to the uterine lining and the resulting formation of a massive discoidal placenta of the deciduate haemochorial type.

In discussing the development of the placenta Professor Hill showed that the trophoblast was unique, both in its histological characters and in its behaviour, and on these grounds concluded that the tarsius placenta was too specialized to have been the actual forerunner of that of the pithecoids, but would seem to have developed along lines of its own, as a parallel formation. Acceptance of this conclusion in regard to the placenta in no way lessened the significance of the tarsioid phase as the more important transitional stage in the evolution of the developmental processes of the primates. It was only necessary to suppose that the pithecoids took origin from another branch of the tarsioid stock in which the attempt at the formation of a haemochorial placenta proceeded along lines comparable with those which were found in the existing pithecoids.

Passing to a consideration of the pithecoid stage, the lecturer said that the justification for the recognition of this stage rested on the occurrence in the platyrrhine and catarrhine monkeys of certain striking resemblances in their early development, all of the nature of definite developmental advances on the tarsioid condition. In this stage the amnion no longer developed by fold formation, since its cavity, the primitive amniotic cavity, arose as a closed space in the ectodermal cell mass of the very early blastocyst. The primary attachment of the blastocyst to the uterine wall was always effected by the trophoblast over the embryonal pole. A second attachment was also usually formed at the anti-embryonal pole, in which case the placenta was bidiscoidal. The extra-embryonal mesoderm and coelom and the mesodermal primordium of the connecting stalk were formed even more precociously than in the tarsioid. The extra-embryonal mesoderm (the so-called primary mesoderm of the early human blastocyst), though homologous with that of the tarsioid, was no longer of direct primitive streak origin, but appeared to arise, as in hapale, as a proliferation from the hinder margin of the shield ectoderm and the adjoining amniotic ectoderm. The trophoblast always became clearly distinguishable into cellular and syncytial layers. The syncytiotrophoblast exhibited erosive and destructive properties, and had the capacity of proliferating and of penetrating more or less deeply into the maternal decidual tissue in the form of an irregular network. The existence of certain well-marked differences in the behaviour of the trophoblast and in the structure of the placenta in the two groups of monkeys, and the very striking similarities in the development of the placenta in the catarrhines and the anthropoids, suggested that the platyrrhines separated very early from the parent stem to pursue a path of their own, while the catarrhines furnished the stock from which the anthropoids originated.

In the anthropoid stage were grouped together anthropoid apes and man, and in this stage was to be seen the culmination of developmental adaptation so far as the primates were concerned. Though there was no knowledge about the earlier stage in the development of the anthropoid apes, enough was known—thanks to the labours of Selenka and Strahl—of their later stages and placentation to justify the belief that their development conformed in all essentials to the human type, so that for the details of early anthropoid ontogeny the work of the human embryologist must be relied on.

The outstanding feature of the early human blastocyst was its extraordinary precocity, as exemplified, for example, in the relations it very early acquired to the uterine lining, and in the remarkably early differentiation of its trophoblast and its extra-embryonal mesoderm. It was no longer content to undergo its development in the uterine lumen, as did the blastocysts of the lower primates, but, while still quite minute, it burrowed its way through the uterine epithelium and implanted itself in the very vascular subepithelial desidual tissue of the uterus. Therein it formed for itself a decidual cavity and underwent its subsequent development, completely embedded in the maternal tissue. In this way the primate germ reached the acme of its endeavour to maintain itself in the uterus and to obtain an adequate supply of nutriment at the earliest possible moment. It was a significant fact that just as the pithecoid blastocyst always attached itself by the embryonal pole, so here that pole was the first to enter, and the embryo lay on the deep side of the blastocyst in immediate proximity to the site of formation of the definitive placenta.

Certain features, distinctive of the anthropoids, were to be regarded as the direct outcome of this process of interstitial implantation, and consequently as purely secondary specializations. These included differentiation of a decidua capsularis from the decidual tissue covering the blastocyst; formation round the very early blastocyst of a complete enveloping network of syncytio-trophoblast, possessing in even more marked degree than that of the pithecoids destructive and penetrative properties; and development from the chorion of the older blastocyst of a more or less uniform covering of chorionic villi. In the blastocyst itself formation of the extra-embryonal mesoderm apparently took place at such an early period that it was able to fill the minute cavity of the blastocyst completely as a delicate cellular tissue in which only later the coelomic cavity appeared.

Apart from these adaptive specializations, the anthropoid developed along the lines laid down in the catarrhine stock, and as a result of the atrophy of the chorionic villi originally related to the decidua capsularis and the growth of those related to the decidua basalis, formed a single discoidal placenta, the homologue of the primary placenta of the catarrhine, and differing from that only in minor details and in the rather more individualized character of its foetal chorionic villi. Of the genetic relationship of the anthropoid apes and man, and of these to the catarrhine stock, concluded Professor Hill, there could be no question on embryological grounds.

British Medical Journal.

SATURDAY, JANUARY 11TH, 1930.

LOCALIZATION OF FUNCTION IN THE NERVOUS SYSTEM.

"PROGRESS of knowledge in regard to the nervous system has been indissolubly linked with the determination of localization of function in it." The truth of this statement by Sir Charles Sherrington might be illustrated from any epoch of the last three centuries of neurological history. But it is noteworthy that there have never been lacking critics of each advance in the theory of the localization of function. It is not surprising that the student, and sometimes even the adept, should find this conflict of opinions confusing. The localizationist can point to certain facts the explanation of which may justly be counted among his triumphs. The Jacksonian convulsion, the hemiplegia resulting from a lesion of the internal capsule, the hemianopia due to destruction of the optic radiation, seem incontrovertible evidence of localization of function. In face of these facts, in what sense must the doctrine of localization be considered inadequate or inaccurate? Dr. James Collier takes this question as the subject of his Savill Memorial Oration, which we publish in this issue (p. 55). Dr. Collier is, we think, right in considering that the information available to the student on this subject is out of date, and his review is therefore opportune. It is to be welcomed as focusing attention on an inquiry which goes to the root of our conceptions of neuro-physiology. This, however, is necessarily a complex question. In one way or another, the problem of the relation between form and function has been at the bottom of most philosophical disputes. The human nervous system is the most complex of living forms; its correspondingly complex functions are as yet only dimly apprehended. It is no wonder, then, that the correlation between these two partially understood complexities should be difficult and incomplete. Nevertheless, a good deal can be done to clear the ground and show how the problem must be approached if it is to be solved.

It is noteworthy that anatomists have played a large part in establishing the localization of neural function, notable examples being Willis, Magendie, and Bell. On the other hand, current criticism of the adequacy of localization theory comes primarily from physiologists, such as Sir Charles Sherrington, Professor Pavlov, and Professor Graham Brown. These facts afford a clue to the source of the apparent conflict. There are two opposite methods of approach to the nervous system, which, for convenience, may be distinguished as the anatomical and the physiological. We employ the anatomical approach when we inquire, "What is the function of the cerebellum, or of the precentral convolution?" We approach the nervous system physiologically when we ask, "What processes underlie movement, co-ordination, sleep, or speech?" Throughout the history of medicine anatomical knowledge has preceded and laid the foundations of physiological knowledge, but physiology requires methods of thought which are alien to anatomy, and for which anatomical education is not the best training. It is clear that the anatomical approach is based on an assumption which is not in fact justified: namely, that morphological distinctions and functional distinctions coincide—that the cerebellum, for example, being a morphological unit, must be a functional unit too, and therefore possesses a discoverable "function," the "function of the cerebellum." Intensive research into the effects of lesions of the cerebellum has greatly added to our knowledge of the symptoms produced by cerebellar destruction, but all attempts to conceive of "the functions of the cerebellum" are vague and unsatisfactory. Lesions of the cerebellum produce widespread disturbances of motility, which is a function of the nervous system as a whole, but the search for "the functions of the cerebellum" is a misapplication of anatomical concepts to the subject-matter of physiology. Still greater confusion arises when the same violence is done to the "higher" functions of speech and thought, as Sir Henry Head has shown. An analogy may be of assistance here. If a pianist suffers amputation of his hands he ceases to be able to play the piano. In what sense is his capacity for piano-playing localized in his hands? His hands are an essential part of the pianist as a piano-playing organism, but it is surely clear that the concept of localization is entirely inapplicable. A neurological parallel would be the state, in respect of motility, of a patient with hemiplegia. His pyramidal tract is a path essential to the function of movement, but motility is not in any sense to be localized there. Just as there are persons in possession of both hands who are unable to play the piano, so there are patients, without muscular weakness, who, having apraxia, are unable to carry out a movement when requested to do so. Even in playing the piano the player possesses considerable latitude as to which finger he shall use to play a given note, and modern researches appear to show that a similar latitude exists in the motor cortex in respect of the movements elicitable at different times from the same small area.

As Dr. Collier concludes, "it is difficult to give up the belief that those regions of the cortex which immediately border upon the junctions of the cortex with the sensory path, the visual path, the auditory path, and the pyramidal path, are more especially connected with the functions these paths subserve." It is indeed unlikely that this belief will ever have to be abandoned. But all these paths are concerned in the most elementary of neural functions, simple conduction of impulses. At this lowly functional level form and function most closely coincide, and there is least discrepancy between anatomical and physiological conceptions. It appears probable that anatomy is reaching the end of its great contributions to neurology, and that we are entering upon an era which will be characterized by the development of neuro-physiological and neuro-psychological concepts in which localization of function will play little or no part.

The interest of neurology has never been purely clinical, and its influence has always extended to psychology and philosophy. Indeed, one of the most important philosophical problems—the problem of knowledge—cannot be solved without its help. At the moment the most pressing need in metaphysics is to bridge the gulf that separates stimulus and sensation, the light wave and the colour. This is not the place to discuss this problem at length, but it is interesting to note that new attempts to solve it are being made on lines parallel to those along which neurology itself is developing. Professor Whitehead, in his recently published Gifford Lectures, "Process and Reality," proposes a solution of the problem of

DEVELOPMENTAL HISTORY OF THE PRIMATES.

PROFESSOR J. P. HILL'S CROONIAN LECTURE.

THE following is an abstract of the Croonian Lecture for 1929, *on the developmental history of the primates*, delivered before the Royal Society by Professor J. P. Hill, F.R.S.

Starting *with the relatively simple developmental conditions* met with in the Lemuroidea, Professor Hill considered the question of how the much more specialized and modified developmental relations found in the higher primates might be supposed to have arisen as the result of adaptive specialization, involving more especially acceleration and abbreviation in the developmental processes. A broad survey of the early development and placentation in representatives of the chief divisions of the order had led to the recognition of four main stages in its evolutionary history—lemuroid, tarsioid, pithecoid, and anthropoid.

The existing lemurs, said Professor Hill, were regarded, from the developmental point of view, as remnants of that basal lemurine stock from which the higher primates took their origin. In their development they exhibited a combination of primitive features with others which were certainly advanced, and which foreshadowed conditions characteristic of the higher types. Primitive features were evinced in the constitution of the blastocyst and its central type of development, in the disappearance of the covering trophoblast and consequent exposure of the embryonal ectoderm, in the origin and mode of spreading of the mesoderm, in the formation of amnion by folds, and in the development of the allantois as a free vesicle. Among the advanced features might be included the relatively early establishment of a complete chorion and its direct and complete vascularization by the ingrowth into it of the allantoic vessels and the reduction of the yolk-sac and its vessels. Their *placentation was regarded as genuinely primitive, and the* lecturer considered the manner in which the more specialized haemochorial type of the higher primates might have been substituted for it.

In the tarsioid stage, as exemplified by the existing tarsius, was to be observed the retention of certain lowly features characteristic of the lemuroids—for example, the exposure of the embryonal ectoderm and the development of the amnion by fold formation. At this stage certain developmental tendencies could be discerned which were already foreshadowed in the lemuroids—namely, the still more precocious differentiation of the extra-embryonal mesoderm, coelom, and chorion, and the replacement of the vesicular allantois by the almost solid connecting stalk, all of them features in which tarsius anticipates the pithecoids. Also present were certain definite advances on the lemuroid, in particular the acquisition by an early blastocyst of a direct attachment to the uterine lining *and the resulting formation of a massive discoidal* placenta of the deciduate haemochorial type.

In discussing the development of the placenta Professor Hill showed that the trophoblast was unique, both in its histological characters and in its behaviour, and on these grounds concluded that the tarsius placenta was too specialized to have been the actual forerunner of that of the pithecoids, but would seem to have developed along lines of its own, as a parallel formation. Acceptance of this conclusion in regard to the placenta in no way lessened the significance of the tarsioid phase as the more important transitional stage in the evolution of the developmental processes of the primates. It was only necessary to suppose that the pithecoids took origin from another branch of the tarsioid stock in which the attempt at the formation of a haemochorial placenta proceeded along lines comparable with those which were found in the existing pithecoids.

Passing to a consideration of the pithecoid stage, the lecturer said that the justification for the recognition of this stage rested on the occurrence in the platyrrhine and catarrhine monkeys of certain striking resemblances in their early development, all of the nature of definite developmental advances on the tarsioid condition. In this stage the amnion no longer developed by fold formation, since its cavity, the primitive amniotic cavity, arose as a closed space *in the ectodermal cell* mass of the very early blastocyst. The primary attachment of the blastocyst to the uterine wall was always effected by the trophoblast over the embryonal pole. A second attachment was also usually formed at the anti-embryonal pole, in which case the placenta was bidiscoidal. The extra-embryonal mesoderm and coelom and the mesodermal primordium of the connecting stalk were formed even more precociously than in the tarsioid. The extra-embryonal *mesoderm* (the so-called primary mesoderm of the early human blastocyst), though homologous with that of the tarsioid, was no longer of direct primitive streak origin but appeared to arise, as in hapale, as a proliferation from the hinder margin of the shield ectoderm and the adjoining amniotic ectoderm. The trophoblast always became clearly distinguishable into cellular and syncytial layers. The syncytial *trophoblast exhibited* erosive and destructive properties, and had the capacity of proliferating and of penetrating more or less deeply into the maternal decidual tissue in the form of an irregular network. The existence of certain well-marked differences in the behaviour of the trophoblast and in the structure of the placenta in the two groups of monkeys, and the very striking similarities in the development of the placenta in the catarrhines and the anthropoids, suggested that the platyrrhines separated very early from the parent stem to pursue a path of their own, while the catarrhines furnished the stock from which the anthropoids originated.

In the anthropoid stage were grouped together anthropoid apes and man, and in this stage was to be seen the culmination of developmental adaptation so far as the primates were concerned. Though there was no knowledge about the earlier stages in the development of the anthropoid apes, enough was known—thanks to the labours of Selenka and Strahl—of their later *stages and placentation to justify the belief that their development* conformed in all essentials to the human type, so that for the details of early anthropoid ontogeny the work of the human embryologist must be relied on.

The outstanding feature of the early human blastocyst was its extraordinary precocity, as exemplified, for example, in the relations it very early acquired to the uterine lining, and *the remarkably early differentiation of its trophoblast and its* extra-embryonal mesoderm. It was no longer content to undergo its development in the uterine lumen, as did the blastocysts of the lower primates, but, while still quite minute, burrowed its way through the uterine epithelium and implanted itself in the very vascular subepithelial desidual tissue of the uterus. Therein it formed for itself a decidual cavity and underwent its subsequent development, completely embedded in the maternal tissue. In this way the primate germ reached the acme of its endeavour to maintain itself in the uterus and to obtain an adequate supply of nutriment at the earliest possible moment. It was a significant fact that just as the pithecoid blastocyst always attached itself by the embryonal pole, so here that pole was the first to enter, and the embryo lay on the deep side of the blastocyst in immediate proximity to the site of formation of the definitive placenta.

Certain features, distinctive of the anthropoids, were to be *regarded as the direct outcome of this process* of interstitial implantation, and consequently as purely secondary specializations. *These included differentiation* of a decidua capsularis from the decidual tissue covering the blastocyst; formation round the very early blastocyst of a complete enveloping network of syncytio-trophoblast, possessing in even more marked degree than that of the pithecoids destructive and penetrative properties; and development from the chorion of the older blastocyst of a more or less uniform covering of chorionic villi. In the blastocyst itself formation of the extra-embryonic mesoderm apparently took place at such an early period that it was able to fill the minute cavity of the blastocyst completely as a delicate cellular tissue in which only later the coelomic cavity appeared.

Apart from these adaptive specializations, the anthropoids developed along the lines laid down in the catarrhine stock, and as a result of the atrophy of the chorionic villi originally related to the decidua capsularis and the growth of those related to the decidua basalis, formed a single discoidal placenta, the homologue of the primary placenta of the catarrhine, and differing from that only in minor details and in the rather more individualized character of its foetal chorionic villi. Of the genetic relationship of the anthropoid apes and man, and of these to the catarrhine stock, concluded Professor Hill, there could be no question on embryological grounds.

LOCALIZATION OF FUNCTION IN THE NERVOUS SYSTEM.

"PROGRESS of knowledge in regard to the nervous system has been indissolubly linked with the determination of localization of function in it." The truth of this statement by Sir Charles Sherrington might be illustrated from any epoch of the last three centuries of neurological history. But it is noteworthy that there have never been lacking critics of each advance in the theory of the localization of function. It is not surprising that the student, and sometimes even the adept, should find this conflict of opinions confusing. The localizationist can point to certain facts the explanation of which may justly be counted among his triumphs. The Jacksonian convulsion, the hemiplegia resulting from a lesion of the internal capsule, the hemianopia due to destruction of the optic radiation, seem incontrovertible evidence of localization of function. In face of these facts, in what sense must the doctrine of localization be considered inadequate or inaccurate? Dr. James Collier takes this question as the subject of his Savill Memorial Oration, which we publish in this issue (p. 55). Dr. Collier is, we think, right in considering that the information available to the student on this subject is out of date, and his review is therefore opportune. It is to be welcomed as focusing attention on an inquiry which goes to the root of our conceptions of neuro-physiology. This, however, is necessarily a complex question. In one way or another, the problem of the relation between form and function has been at the bottom of most philosophical disputes. The human nervous system is the most complex of living forms; its correspondingly complex functions are as yet only dimly apprehended. It is no wonder, then, that the correlation between these two partially understood complexities should be difficult and incomplete. Nevertheless, a good deal can be done to clear the ground and show how the problem must be approached if it is to be solved.

It is noteworthy that anatomists have played a large part in establishing the localization of neural function, notable examples being Willis, Magendie, and Bell. On the other hand, current criticism of the adequacy of localization theory comes primarily from physiologists, such as Sir Charles Sherrington, Professor Pavlov, and Professor Graham Brown. These facts afford a clue to the source of the apparent conflict. There are two opposite methods of approach to the nervous system, which, for convenience, may be distinguished as the anatomical and the physiological. We employ the anatomical approach when we inquire, "What is the function of the cerebellum, or of the precentral convolution?" We approach the nervous system physiologically when we ask, "What processes underlie movement, co-ordination, sleep, or speech?" Throughout the history of medicine anatomical knowledge has preceded and laid the foundations of physiological knowledge, but physiology requires methods of thought which are alien to anatomy, and for which anatomical education is not the best training. It is clear that the anatomical approach is based on an assumption which is not in fact justified: namely, that morphological distinctions and functional distinctions coincide—that the cerebellum, for example, being a morphological unit, must be a functional unit too, and therefore possesses a discoverable "function," the "function of the cerebellum." Intensive research into the effects of lesions of the cerebellum has greatly added to our knowledge of the symptoms produced by cerebellar destruction, but all attempts to conceive of "the functions of the cerebellum" are vague and unsatisfactory. Lesions of the cerebellum produce widespread disturbances of motility, which is a function of the nervous system as a whole, but the search for "the functions of the cerebellum" is a misapplication of anatomical concepts to the subject-matter of physiology. Still greater confusion arises when the same violence is done to the "higher" functions of speech and thought, as Sir Henry Head has shown. An analogy may be of assistance here. If a pianist suffers amputation of his hands he ceases to be able to play the piano. In what sense is his capacity for piano-playing localized in his hands? His hands are an essential part of the pianist as a piano-playing organism, but it is surely clear that the concept of localization is entirely inapplicable. A neurological parallel would be the state, in respect of motility, of a patient with hemiplegia. His pyramidal tract is a path essential to the function of movement, but motility is not in any sense to be localized there. Just as there are persons in possession of both hands who are unable to play the piano, so there are patients, without muscular weakness, who, having apraxia, are unable to carry out a movement when requested to do so. Even in playing the piano the player possesses considerable latitude as to which finger he shall use to play a given note, and modern researches appear to show that a similar latitude exists in the motor cortex in respect of the movements elicitable at different times from the same small area.

As Dr. Collier concludes, "it is difficult to give up the belief that those regions of the cortex which immediately border upon the junctions of the cortex with the sensory path, the visual path, the auditory path, and the pyramidal path, are more especially connected with the functions these paths subserve." It is indeed unlikely that this belief will ever have to be abandoned. But all these paths are concerned in the most elementary of neural functions, simple conduction of impulses. At this lowly functional level form and function most closely coincide, and there is least discrepancy between anatomical and physiological conceptions. It appears probable that anatomy is reaching the end of its great contributions to neurology, and that we are entering upon an era which will be characterized by the development of neuro-physiological and neuro-psychological concepts in which localization of function will play little or no part.

The interest of neurology has never been purely clinical, and its influence has always extended to psychology and philosophy. Indeed, one of the most important philosophical problems—the problem of knowledge—cannot be solved without its help. At the moment the most pressing need in metaphysics is to bridge the gulf that separates stimulus and sensation, the light wave and the colour. This is not the place to discuss this problem at length, but it is interesting to note that new attempts to solve it are being made on lines parallel to those along which neurology itself is developing. Professor Whitehead, in his recently published Gifford Lectures, "Process and Reality," proposes a solution of the problem of

knowledge which entails a revision of current conceptions of localization both in the world of space and in the nervous system. Perhaps the neurologist of the future will look back upon the neurology of to-day as the relativitist regards Euclidean geometry. Even then, however, the student will still have to learn the course of the pyramidal tract.

CANINE DISTEMPER.

ABOUT seven years ago, as our readers will remember, a fund was inaugurated by the *Field* for the purpose of investigating the cause of distemper in dogs, and of finding, if possible, a practicable preventive. The work was undertaken at Mill Hill by the Medical Research Council because, although the disease is not transmissible to man, distemper is an acute infectious fever comparable to human influenza, and it was hoped that a study of the canine condition would lead to a better understanding of the human disease. The work took some time to get under way, as it was necessary to breed dogs in a carefully isolated area where they would be entirely free from outside contamination. Fortunately, however, it was discovered that the ferret was susceptible to the disease, and this animal has proved to be an invaluable laboratory aid throughout the investigations, and has considerably accelerated progress.

Dr. Laidlaw and Mr. Dunkin have been able to prove that the infectious agent is a filterable virus, thus confirming the claim made by Carré in 1905 and generally accepted by most responsible workers in this country—although received much less favourably abroad. They found that the virus could be transmitted by the blood and tissues of distemper cases through an indefinite series of animals, though the infective material appeared to be sterile in all known culture media. No bacteria were found, and it is now accepted that the various organisms previously associated with the disease are really secondary invaders. There is no reason, of course, why some or all of these should not cause disease by themselves, but such disease is not distemper. This term has been very loosely used in the past, and it is now known that several different infections were grouped under a common name. True distemper is due to a filterable virus, and, so far as is known, only one strain of this virus exists. It has also been found that this virus can be very easily killed or inactivated, and that, provided this treatment is not too drastic, the inactivated virus forms an efficient vaccine. Such a vaccine is now being prepared commercially, both in this country and in the United States, by the treatment of virus with formol; unfortunately, however, until a method is found of preparing the virus *in vitro*, recourse must be had to the crude virus in the lymph glands, spleen, and liver of infected animals. It has been found possible, with a single injection of this vaccine, to produce a resistant state in over 90 per cent. of ferrets and dogs. This resistant state is converted into a solid immunity by the subsequent administration of living virus. In the majority of cases this immunity proves to be complete, though in some cases there has been a short reaction. In under 1 per cent. death resulted; in a number of cases this was undoubtedly due to the fact that the dog, when vaccinated, was actually infected with the natural virus and in the incubative stages of the disease.

So far the work has been concerned with preventive measures, but now the workers are directing their attention to curative treatment. A vaccine is obviously of little use in an acute infectious fever, and so work has been concentrated on the production of a serum. A hyper-immune serum has already been produced at Mill Hill which, in a 10 c.cm. dose, produces an immediate passive immunity in a susceptible dog; dogs given a dose of virus simultaneously—but on opposite sides of the body—frequently proved to be immune to subsequent injections of virus alone. Work has not yet progressed to a stage where the exact dose can be stated, or the time required for the production of immunity be estimated accurately, and attention is at present being directed mainly towards the discovery of some means for the evaluation and standardization of different serums. The serum does, however, prevent an attack if given in the incubative period of the disease; and it can cut short an attack and prevent the development of the secondary febrile stage if given at the beginning of the primary stage. The serum would seem, therefore, to have obvious practical applications, but given alone the passive immunity only lasts for nine days and confers no permanent protection on the animal, although it may tide it over a dangerous period.

Considerable progress has thus been made with the investigations on the distemper virus. The results show, however, that it is merely a special case of protection by means of dead or inactivated virus. Very similar results have been obtained with other virus diseases, such as rabies, cattle plague, fowl plague, and foot-and-mouth disease, the latter being complicated by the fact that at least three strains of virus exist with no cross-immunity. The application of the results obtained in these animal diseases to analogous diseases in man has so far proved disappointing, and it is only where the human disease is found naturally in animals, as in rabies, or is experimentally transmissible to them, as in yellow fever, that progress has been possible. Until a method is found of obtaining large quantities of virus *in vitro*, it seems unlikely that we shall be able to employ an effective vaccine against such purely human diseases as influenza. It is not safe to be dogmatic about this, as it is only in very recent years that Indian monkeys have been found to be susceptible to yellow fever, and Chinese hamsters to kala-azar. Even though an experimental or natural host is found for influenza, it would obviously be much more satisfactory to discover some method of raising artificial cultures, and it is along these lines that future work must expect to obtain its most effective results.

DIFFICULT CHILDREN.

THOUGH now receiving prominent attention the problem of the difficult maladjusted child is of course as old as human nature. As Dr. G. A. Auden[1] has lately recalled, it was familiar to Plato and was forcibly brought before Jerome Cardan of Milan, famous mathematician, physician, and voluminous author in the sixteenth century, by the crimes of his two sons, in spite of the assurance of the horoscope cast by himself that "the nativities of my sons promise me much good and little harm." Within comparatively recent years several circumstances have combined to bring this important problem into the open field of practical consideration and action. Perhaps the most obvious of these is the influence of the war and its attendant effects, including the appearance of what was a newly recognized disease, epidemic or lethargic encephalitis; but there are others, such as the rise of eugenics, the increased activity in educational matters, and perhaps a more general appreciation of the altered relations between parents and children, the handicap of

[1] Auden, G. A.: *Journ. Roy. Sanit. Instit.*, 1929, l, 157; *Journ. Ment. Sci.*, 1929, lxxv, 220.

the only child, and the tragedy of the unwanted child. The need for investigation of maladjusted children and for their efficient treatment has now been recognized and acted upon. In London there are clinics for them at Guy's and University College Hospitals in connexion with the out-patient departments; at the Maudsley Hospital a children's clinic is held twice a week, and the Tavistock Clinic sees an increasing number of child patients. The Jewish Health Organization has for five years had a clinic at Spitalfields; the clinic at Clarendon Road, at the opposite end of the metropolis, has just issued its first annual report, and the Child Guidance Council, aided by a generous grant from the Commonwealth Fund in New York, has recently opened a fine clinic in Canonbury Place, Islington. There are also clinics at work in Bath, Brighton, Edinburgh, Glasgow, Portsmouth, Stoke-on-Trent, and elsewhere. The problem is complex, and therefore demands for its successful solution team work on broad lines, so that the educational, psychological, psychiatric, medical, and other aspects, such as the home environment reported on by a social worker, should all be surveyed and accurately correlated in their due proportion. The staff of the clinics should therefore be composed of workers skilled in these various lines and anxious to join in conferences rather than to pursue an individual course. This may appear too obvious a truism, but at the recent discussion, opened by Dr. Bernard Hart, at the Psychiatric Section of the Royal Society of Medicine on December 10th, 1929,[1] it was pointed out by Dr. H. C. Cameron that the scheme of these clinics was incomplete without a paediatrician, because the basis of the psychiatric condition of the child might be metabolic. This consideration has a direct bearing on a reasonable contention put forward by Dr. R. D. Gillespie in a letter printed lately in our columns.[2] Dr. Gillespie argues that these special clinics should be associated with general hospitals, where expert advice and investigation into the medical and metabolic factors can be readily obtained. Often, no doubt, two or more factors are responsible, and to neglect one might easily lead to failure. One advantage of an intimate association between these special clinics and teaching hospitals is that further opportunity would thus be available for the students (who seem to be more generally interested in the psychological aspects of medicine than were their forebears) of gaining practical experience in the methods of investigating and treating difficult, nervous, and maladjusted children. As already mentioned, co-ordinated or team work is especially necessary in connexion with this subject. The earlier in his clinical years that the student gets a taste for the psychological aspects of medical practice the better will he be equipped for his life's work; and his active interest will make him disinclined to throw the whole burden of investigation on the educationist and the lay psychologist.

RECURRENT DISLOCATION OF THE SHOULDER.

THE November, 1929, number of the *Revue d'Orthopédie et de Chirurgie de l'Appareil Moteur*, which has just reached us, contains a report of the discussion on recurrent dislocation of the shoulder-joint, which was opened by Dr. Tavernier of Lyons in Paris on October 11th, 1929, M. Albert Mouchet being in the chair. We published an abstract of Dr. Tavernier's paper in our issue of October 19th, 1929.[3] Comprehensive and interesting as that paper was, the discussion was hardly worthy of it, for only two speakers on it are reported. Perhaps the very completeness with which Dr. Tavernier treated his subject may have rendered discussion unnecessary in the opinion of most of his hearers. Dr. Mauclaire of Paris said that he had explored the joint and observed the explorations of other surgeons in these cases. His conclusions as to their morbid anatomy were that, although the capsule was often distended, as often it was normal in volume. He had never seen the posterior groove described by some. He had often found detachment of the perio-teum in front and chipping (*echancrure*) of the anterior border of the glenoid cavity, and also often mallet- or hatchet-shaped deformity of the humeral head. This implied a displacement of the axis of the shaft in the sense that the centre of the head no longer corresponded with the centre of the glenoid cavity. It was eccentric. The lesions present were very various, according to the case, and the pathogeny therefore not uniform. Hence different operative techniques were indicated in different cases. Dr. Mauclaire had done capsulorrhaphy in his earlier cases, and had seen relapses follow in epileptics. He found the myoplastic operation of Clairmont-Ehrlich difficult on account of the shortness of the musculo-tendinous transplant. He had a good result from osteo-periosteal bone grafts inserted in front of and below the glenoid cavity. The patient on whom this operation was done in 1923 had had no recurrence, despite an active life involving the carrying of heavy loads. Dr. Mauclaire suggested that the combination of such an operation with Oudard's method of lengthening the coracoid process, as practised by Lenormant, was worth trying. Dr. Rocher of Bordeaux reported the case of a soldier on whom he had performed the operation of Oudard (lengthening the coracoid process). He thought that it constituted a great advance in the treatment of recurrent dislocation of the shoulder.

MILK VERSUS COD-LIVER OIL.

IN the Danish journal *Ugeskrift for Laeger* (October 3rd, 1929, p. 852), H. R. Krogsgaard describes an investigation he carried out on the relative value of milk and cod-liver oil to growing children. The subjects of the investigation, boys living under the same conditions in a school in Denmark, were divided into three groups, of which the first, containing thirty-four boys, received a daily extra ration of 9 oz. of fresh milk, the second, containing thirty-three boys, served as control, and the third, containing eighteen boys, received a daily extra ration of a tablespoonful of cod-liver oil. The experiment was started on March 1st and ended on June 4th. Once a month the boys were weighed and measured for height, and the permanence of the results was checked by measurements taken on June 30th. In the first month the milk group forged ahead rapidly, with an average gain in weight of 7 lb. 5 oz., in contrast with the control group and the cod-liver oil group, whose average gain was only 1 lb. 1½ oz. and 12 oz. respectively. But on June 4th the differences were not so marked; the milk group failed to sustain its initial spurt, and its average gain was now only 2 lb. 6 oz.; of the control group it was 3½ oz., and of the cod-liver oil group it was 7 oz. On June 30th, when the permanence of the result was tested, it was found that the differences in the three classes had been almost wiped out, the average gain of weight over the whole period for the three groups being respectively 1 lb. 1½ oz., 12 oz., and 14 oz. In respect of increased height the cod-liver oil group proved, in the long run, to be better than the milk group. During the actual period of the experiment the average increase in the milk group was 0.5 inch, and by June 30th it had reached nearly 0.6 inch. In the control group the corresponding figures were 0.3 inch and 0.7 inch, and in the cod-liver oil group they were 0.1 inch and 0.8 inch. The surprising fact was that the cod-liver oil group, which had at first lagged behind the others, eventually beat them both. Krogsgaard's expectation that the underweight children in the

[1] *British Medical Journal*, December 21st, 1929, p. 1160.
[2] *Ibid.*, December 28th, 1929, p. 1219.
[3] "Recurrent Dislocation of the Shoulder," *British Medical Journal*, October 19th, 1929, p. 732.

cod-liver oil and milk groups would show the greatest gains was not fulfilled. In the cod-liver oil group there were ten children who were 7 per cent. under-weight in relation to their height; at the end of the experiment they were 8.4 per cent. under weight. In the milk group there were also ten underweight children; their average underweight in relation to height before the experiment was 9 per cent., and at the end of the experiment this figure was reduced to 7.5 per cent. It would seem that whereas the boys in the cod-liver oil group had developed in height rather than in weight, those in the milk group had spent their extra ration in growing heavier rather than taller. In respect of absences from school because of sickness the cod-liver oil group did best, the figure arrived at by dividing the number of days of sickness by the number of children being in this group 0.57, in the control group 2.62, and in the milk group 2.10. It was only during the period of the experiment that the three classes showed these striking differences in sickness rate. Krogsgaard concludes that the addition of milk to the dietary of school children of average weight brings about only a temporary gain of weight, and none at all in underweight children. Cod-liver oil, he suggests, not only promotes gain of height, but also a reduction of the sickness rate.

SIGHT TESTING IN AMERICA.

"THE diagnosis of eye symptoms and treatment of eye-strain should, so far as possible, be done by men and women educated in medicine." With these words ends a reasoned statement on the conditions attending eye work presented by the Committee on Optics and Visual Physiology of the American Medical Association at the annual meeting of 1929.[1] The experience of a century has shown how large is the number of persons with errors of refraction that demand treatment. Presbyopia comes to all with age; *myopia is a common affection of school life;* hypermetropia may lead to poor sight and strain, and astigmatism is worse. All these may cause serious strain of the nervous system. Errors of muscle balance have equally bad effects. Aching eyes, vertigo, nausea, nervous dyspepsia, malnutrition, hyperaesthesia, mental depression, melancholia, and illusions may be due to the nerve strain of trying to avoid blurring, or double vision, produced by ocular defects, and can be prevented or removed by wearing proper lenses or prisms. These facts, and the need for determining what share ocular defects may have in producing symptoms that might arise from other causes, make accurate correction of eye troubles imperative. This work *cannot be done by men ignorant of medicine,* by those who estimate success by the profit on glasses sold, by manufacturers trying to control the market by copyrighted names for their goods. Commercialism must not dominate either the eye physician or the optician. According to the report, "there has been an energetic, persistent effort on the part of aggressive optometrists to secure and to keep up a confusion in the public mind with regard to the different classes of advertisers who claim to measure the refraction of the eye and correct it with glasses. Some seek the degree of Doctor of Optometry, Doctor of Optics, or a similar title from commercial schools chartered to confer such degrees. They like to be called 'Doctor' by their customers, whom they speak of as 'patients,' and by everyone else who will help them extend the impression that they know something about medicine applied to the eye." The committee makes caustic references to the custom, prevailing among some ophthalmologists, of using non-medical assistants, or referring their refraction work to juniors, and urges the section to promote a wider understanding of visual physiology and optics, and their practical application to the needs of eyes subjected to the requirements of vision in our civilization.

[1] *Journ. Amer. Med. Assoc.*, November 9th, 1929, p 1410.

SURGICAL INSTRUMENTS AND CURIOSITIES.

THE Council of the Royal College of Surgeons of England has added to its benefactions to the surgical public by publishing Mr. C. J. S. Thompson's account of the surgical instruments and other objects in the historical section of the Museum.[1] In 1928 a *Catalogue of the Manuscripts in the Library* was printed, but not, so far as we know, placed on sale, as is the guide now issued. No more competent historian of the collection could be found than Mr. Thompson, a worthy successor to the late Mr. Alban Doran, to whom so much of the original work of describing and cataloguing was due. One of the most attractive features of this collection is its eclectic character. Here is no rigidly specialized exhibition of surgical tools, but rather a kind of *omnium gatherum* of objects of human interest ranging from an artificial leg of the third century A.D. to a cast of the humerus of Dr. Livingstone, showing the healed fracture by which the body was identified. There is a collection of tourniquets, including, of course, Petit's, which held the field from 1713 till that of Esmarch superseded it. We learn from Mr. Thompson that the very name of "tourniquet" was due to Petit. It is rather strange that in all the pictures of battles which we have seen there is no trace of blood. In those of the death of Nelson, the *Victory's* quarterdeck, which must have been like a shambles, is represented as spotlessly clean. Yet no means of preventing haemorrhage are represented, except in one instance, a mezzotint in colours in the Macpherson collection of naval paintings and prints, which was exhibited in the Guildhall Art Gallery, London, in the autumn of 1928. This print shows Captain Trollope of the *Glatton* in 1796 insisting that the wounded Captain Strangways, who commanded the marines, should go below. A screw tourniquet of the Petit type is represented on Strangways's thigh, outside his knee-breeches; the pad of the tourniquet is placed over the front of the middle of the limb instead of over the line of the femoral artery, but there is not a drop of blood visible anywhere! Professor Geoffrey Callender, the custodian of the collection, tells us that he has seen no other representation of a tourniquet in many thousands of prints of naval actions. Sir Gilbert Blane has left it on record that when he was with Rodney at the battle off Dominica in the West Indies, having no duties below, he provided himself with dressings and two or three tourniquets and took up a position on the quarterdeck, where he thought that he might be of service to wounded officers, for he had known of a number of cases in which wounded officers or men, while being carried below, had died for the want of a tourniquet and first aid. Among the curiosities in the Historical Room are a heavy chain and stout leather belt, which were found in an old house in Stoke Newington, and are supposed to have been used to restrain a lunatic in the bad old days when chains, straw, and whips were recognized means of treating mania. Chastity belts, the hands of Thomas Beaufort, mummies, and shrunken heads from South America, are to be seen there. Readers of the *Mysteries of Udolpho* and of *Northanger Abbey* will remember the mystery of the picture frame covered with a black veil, on lifting which the too sensitive Emily incontinently indulged in one of her many fainting fits. It is not till near the end of the third volume that the reader is told that the veiled horror was a representation in wax of a partially decomposed corpse. Although Mrs. Radcliffe knew little of Italy, she seems to have been well informed in this respect, as the following entry in the guide shows: "A 'Memento Mori,' modelled in wax by Zombo or

[1] *Museum, Royal College of Surgeons of England: Guide to the Surgical Instruments and Objects in the Historical Series, with their History and Development.* By C. J. S. Thompson, M.B.E. With a foreword by the Conservator, Sir Arthur Keith, M.D., F.R.C.S., F.R.S. Issued by order of the Council. London: Taylor and Francis. 1929. (2s. 6d.)

Zambo of Naples in 1660. Models illustrating the human body in the first stages of decomposition were executed with great fidelity by several Italian sculptors. Zombo, who became famous in the XVII century, carried out his models in coloured wax." Beside such things as these the collection of instruments and appliances used by Lister and the historical series of stethoscopes may seem tame, but there are many other articles of great interest described in the guide, which we hope may have a wide circulation and make better known some of the treasures stored in the college buildings and the Hunterian Museum.

FEMALE SEXUAL HORMONES.

THE general effect of recent advances in our knowledge of the female sexual hormones has been to reveal a system of hormonic control of hitherto unsuspected complexity. The problem, moreover, is complicated by much confusion in the nomenclature. Professor Ernst Laqueur of Amsterdam has made important discoveries in this field, and therefore his views are of particular interest. In a recent Mayo Foundation Lecture[1] he has given a short summary of the properties of menformon (or ovarian hormone) as determined by his school. His main conclusions are as follows. The hormone produces four chief effects. The first effect is the appearance of oestrus in castrated animals. This reaction is used in biological standardization, and the purest preparations contain 10,000 mouse units per milligram. Such preparations are protein-free. A second effect is the inducing of growth of juvenile genitalia and of atrophic genitalia. A third effect is the stimulation of growth of the mammary gland. This, however, is only produced in certain animals; it occurs, for instance, in the guinea-pig, but not in the goat. A fourth effect, in males, is inhibition of the growth of the testes and of the development of male secondary sexual characters in juvenile animals. The hormone also increases metabolism in castrated females. Menformon is certainly not the only female sexual hormone, but it is the one whose characters are best established at the present time.

HEALTH OF PALESTINE.

THE Department of Health of Palestine, in its report for 1928, is able to record a small decline in the infant mortality rate, but confesses that, with the figure at 186.34 per 1,000 for the whole country, and 203 per 1,000 among the Moslem population, it cannot yet hope to bring the rate down to that prevailing in England and America. The relatively low figure of 95.89 for the Jewish population is attributed partly to the interest of this section of the community in maternal and infant welfare, and partly to the fact that the Jewish mothers are comparatively young and healthy. The total birth rate of 53.98 compares with 50.35 in 1927, and the Moslem birth rate has risen to 60.99, an increase which the department regards as a sign of improving health and virility among both the urban and rural populations. The number of admissions to hospitals and attendances at dispensaries continues to be high, the Jewish population being particularly fortunate in the facilities provided for them, and the fellahin as well as the effendi taking every advantage of their opportunities of obtaining medical treatment. In general, however, services on behalf of the pregnant woman, infants, and children among the Arab population are inadequate, their extension being retarded by the fact that it is impossible to obtain a sufficient number of trained women of the right stamp. The department records with satisfaction that the standard of school medical service throughout the country has been well maintained. The health of the children, both in Arab and Jewish schools, is remarkably good, while the training in hygiene and the elements of mental science, and, in the girls' schools, in infant welfare, is having a beneficial influence on the pupils and producing a reaction on their own and their families' characters.

SCIENTIFIC MUSEUM AT THE WINNIPEG MEETING.

IN connexion with the ninety-eighth Annual Meeting of the British Medical Association at Winnipeg next August, a museum of scientific exhibits and pathological specimens is being organized under the chairmanship of Dr. J. C. Boileau Grant. Arrangements have been provisionally made for five groups—namely, exhibits bearing on papers and discussions in the various Sections; specimens and illustrations relating to any recent research work; instruments associated with clinical diagnosis or pathological investigations; a series of specimens of special interest; and a large exhibit of *x*-ray films. Those intending to send such films are asked to arrange that, so far as possible, they shall be reduced to 8 by 10 inches, since cabinets are being constructed for these dimensions. The organizing committee of the museum wishes it to be understood that in addition to these groups provision can be made for members to exhibit other specimens, illustrations, photographs, lantern slides, casts, or microscopical preparations bearing on any special subject. Every possible care will be taken of such specimens, and the contents of the museum will be insured. Arrangements can be made for contributors to demonstrate their exhibits. The museum will occupy a central position, adjacent to the main auditorium, in the building which houses the commercial exhibits, recreation rooms, and registration offices. Members in a position to send scientific exhibits or pathological specimens should communicate as soon as possible with the honorary secretary of the organizing committee, Dr. Daniel Nicholson, Medical College, Winnipeg, Canada.

THE THANK-OFFERING FUND.

AFTER the closing, early in December, of the Thank-offering Fund, the general council of King Edward's Hospital Fund for London, of which the Prince of Wales is president, submitted an address to the King, describing the origin, history, results, and distribution of the Thank-offering Fund, and tendering loyal congratulations to His Majesty on his recovery. The address included the financial details set out in our columns on December 21st, 1929 (p. 1166), and recalled that this Fund was only the first of many others which sprang up all over the country. The total amount of money so raised is as yet unknown, but it is believed that what was received by King Edward's Hospital Fund does not represent more than a fraction of a very large sum. The King, in reply to the address, expressed his appreciation of the manner in which the Thank-offering Fund has been administered, and of the widespread response to the various other funds throughout the country.

THE General Medical Council is undertaking a new cycle of inspection of final examinations in medicine, surgery, and midwifery, in accordance with Section 3 (2) of the Medical Act, 1886, and has appointed for this purpose the following inspectors: Medicine, Professor T. Wardrop Griffith; Surgery, Mr. Farquhar Macrae; Midwifery, Dr. John S. Fairbairn.

WE regret that in the list of New Year honours published last week we overlooked the name of Dr. Russell Facey Wilkinson, physician to H.R.H. the Princess Royal, who has been created K.C.V.O.

THE PATHOLOGY OF RAYNAUD'S DISEASE.

AN EXPERIMENTAL STUDY.

IN our issue of July 20th, 1929 (p. 111) we gave some account of the third Victor Horsley Memorial Lecture, in the course of which the lecturer, Sir Thomas Lewis, M.D., F.R.S., described some observations relating to the mechanism of Raynaud's disease which he had carried out in association with Professor William Kerr. A full account of these observations appears in a monograph entitled "Experiments relating to the peripheral mechanism involved in spasmodic arrest of the circulation in the fingers, a variety of Raynaud's disease," which was first printed in *Heart* (vol. xv, No. 1, August, 1929). The studies were undertaken from a desire to demonstrate that the methods of investigating the physiology of the cutaneous vessels described in Sir Thomas Lewis's monograph *The Blood Vessels of the Human Skin and their Responses* could be extended to specific clinical problems, and Raynaud's disease was chosen as the malady most suited for this purpose. It is generally acknowledged that underlying this malady is an obstruction of the blood flow to the digits, and the experiments were devised to determine the site of this obstruction, its nature, and the way in which it is brought about. Upon these matters there has been no unanimity of opinion, nor, indeed, has any important knowledge been added since 1862, and again in 1874, when Raynaud published his own writings on the subject. The authors suggest that the reason for this slow advance is that workers have been content to follow the purely observational methods, and they decided, therefore, in their own work to use the method of experiment. To this end they investigated the condition of the hands during actual attacks, tried to discover precisely the circumstances in which such attacks occur and subside, and then proceeded to induce attacks and to analyse the mechanism underlying them.

Onset of Attacks and Recovery.

An "attack" is defined as the occurrence of a full cyanotic tint (with or without pallor) in such parts of the hand as are accustomed to present it periodically. After careful study it became possible to determine in most patients the particular conditions under which an attack would occur, and to induce it by various means almost at will. Early in the investigation it was found that undue cooling of the hand failed to bring on an attack under experimental conditions, and that suitable temperatures lay between 10° and 22° C. There are several reasons for the failure of the lower temperatures: (*a*) The minute vessels of the skin of these patients react as do those of normal skin to excessive cold by dilating; pallor tends not to occur, therefore. (*b*) At these temperatures dissociation of oxyhaemoglobin does not occur, or occurs only slightly; this hinders or prevents cyanosis. (*c*) Excessive cold induces an after-reaction in the skin, tending to dilate the arterioles: this reaction, by establishing a flow of blood through the skin, maintains a healthy-looking colour. In all the patients recovery was brought about at a room temperature of 20° C., though the time taken for this to occur varied from a few minutes to an hour or more. In most patients it appeared abruptly, the colour of the fingers changing from violet to bright red, and their temperature rising and remaining high. These changes indicate an abrupt and wide opening of vessels previously in spasm, and a consequent flooding of the finger with fresh oxygenated blood. In some patients partial recovery occurred, some parts of the fingers turning red, but not showing a rise of skin temperature. An important characteristic of those with severer type of disease is that the temperature of their fingers corresponds closely to that of the surrounding air. In the colder months, therefore, there would be frequent periods of exposure to cold during which the circulation of the fingers stops altogether: the intervals between are periods not of normal flow, but of very slight flow. These facts serve to explain why nutrition in the fingers suffers, and why from time to time portions of the tissue come away in the form of dry gangrene. In normal subjects Sir Thomas Lewis has found that the finger reacts to over-cooling—for example, to immersion in water at 0° C. for five or ten minutes, by becoming several or even many degrees centigrade hotter than its neighbours. This reaction, which has an important protective function, is normally at its height about fifteen or twenty minutes after the end of immersion, and continues for about forty to sixty minutes. In patients with severe Raynaud's disease, however, there is no appreciable rise of finger temperature after over-cooling. The compensatory increase of blood flow, owing to a counteracting spasm of the vessels, suffices only to redden the fingers. Observations were made showing that at a surrounding temperature of 30° C. the vessels even in severe cases were capable of an expansion giving a blood flow not far short of normal.

The Vessels Involved in the Spasm.

It is generally believed that during attacks of discoloured fingers the circulation in the skin is brought to a standstill. To estimate the amount of blood flow the authors used a colour scale ranging from the red of flushed skin to the tint of full cyanosis, and matched the colour of the fingers with the colours in the scale. In attacks of cyanosis the portion of the finger affected is its distal part, the tip, the last phalanx, the last two phalanges, or the whole finger. The march is usually from the distal part to the proximal; and, if there is successful recovery, the order is reversed. Some authors hold that the veins of the affected fingers are in a state of spastic contraction. Sir Thomas Lewis and his co-worker have observed, however, that if during an attack the hand is raised above the head the cyanosed fingers become paler, darkening again when the hand is lowered; in other words, that dark-coloured blood flows into or out of the minute vessels of the fingers when the arm is depressed or elevated. This test demonstrates the existence of an open pathway from minute vessels to veins and vice versa, for blood entering from the arteries would have produced reddening and not darkening of the skin. The vessels involved in the spasm were traced by warming different parts of the hand selectively. If the palm alone was warmed the fingers recovered slowly, proving that vessels in the palm were in spasm. Confirmatory evidence was afforded by studying the effect of local cooling of the palm while keeping the fingers warm. It was found that the vessels in the fingers corresponding to the cooled part of the palm went into the spasm. The mechanism of an attack appears to be a closure, at relatively low temperatures, of relatively large vessels; this closure is believed not to be reflex in nature, there being no evidence that vasomotor impulses, when weakly aroused, confine themselves to the tips of the digits, or that, as the nerve impulses increase in force, their influence spreads in stages in a proximal direction. Moreover, vasomotor reflexes created by cold are known to be conveyed very widely and not to limit themselves to the small skin territory to which cold has been applied. The authors are thus led to the conclusion that in patients with Raynaud's disease there is an abnormality of the arteries displaying itself in hypersensitivity to relatively low temperatures, and that the effects of cold are not produced through the intervention of the nervous system.

Blanching of the Skin during Attacks.

Great stress has been laid in the past on pallor of the fingers during an attack; by matching the colours of such fingers with the standard colour scale it has been found, however, that the extent of pallor has generally been overestimated, and that an equal amount can be induced in the pale hands of some normal subjects by temporarily arresting the circulation. The theoretical importance of a blanched skin lies in the fact that simple arterial obstruction will not produce it, provided that, as is usual, the hands lie below the level of the heart, and in the fact that a strong vaso-constrictor nervous impulse can probably produce full blanching of the skin by causing contraction of the minute vessels. If, therefore, it can be shown in patients with Raynaud's disease that blanching of the fingers is due to active contraction of the minute vessels, then this phenomenon, in the absence of some other equally reasonable explanation, would constitute evidence favouring the hypothesis of vasomotor impulses. Among the large number of spontaneous and provoked attacks seen by the authors not one started with blanching of the skin; the initial phenomenon was always cyanosis. Moreover, in not a single case of the series has blanching of the skin been an essential feature of attack; the blanching that does occur is due more often than not to movement and friction, giving place to cyanosis when the hands are held at rest. There is a second type, however, which holds for much longer periods when the hands

are at rest. In this form the minute vessels are actively contracted, their tone being broken down only by continued exposure to a pressure of 40 mm. Hg. The authors believe this active blanching to be analogous to the production of Bier's spots, or to the universal blanching of the skin after death, and in one of the patients they have reproduced the phenomenon of blanched finger by arresting the circulation to the arm.

The Role of the Vasomotor Nerves.

To gather further evidence about the influence of the vasomotor nerves upon spasm of the digital arteries, the authors have studied the effects on patients on anaesthetizing the ulnar nerve. The resulting vasomotor paralysis sufficed to redden the affected skin area, but not to raise its temperature if the hand were cold. By cooling the hand it was possible to induce a spasm in the fingers supplied by the anaesthetized ulnar nerve, and though full cyanosis was not always maintained there was evidence that the arterial spasm became practically complete. The authors, on the basis of physiological experiment, believe that the vaso-constrictor nerves pass to the vessels of the limb in the mixed nerve, and not along the arterial coats. It would follow, therefore, that complete anaesthetization of the ulnar nerve blocks all vaso-constrictor paths to the fifth finger; yet the authors, having paralysed the main and probably the only vaso-constrictor supply, were still able, by means of appropriate local stimulus of cold, to produce vascular spasm. Hence the abnormal spasm of the spontaneous attack must be produced locally, and does not arise primarily out of abnormal vasomotor impulses. The results of surgical interferences with the vaso-constrictor nerve supply have, in the opinion of the authors, been insufficiently tested by exact observation to serve as evidence in favour of a vasomotor origin of the spasm. They do not, however, intend to suggest that because a vasomotor impulse does not determine the abnormal condition of spasm it contributes nothing to the tone of the vessels.

THE SOCIETY OF APOTHECARIES.

MINISTER OF HEALTH AT YEOMANRY DINNER.

THE Yeomanry Dinner of the Society of Apothecaries of London was held in the Hall of the society at Blackfriars on January 7th, when about one hundred sat down under the presidency of the Master, Lieut.-Colonel C. T. SAMMAN. The principal guest was the Minister of Health (the Right Hon. Arthur Greenwood, M.P.), and among others present were Mr. Justice Humphreys, Mr. Justice Rowlatt, Sir Humphry Rolleston, Sir E. Farquhar Buzzard, Sir Walter Fletcher, Sir Andrew Balfour, and Dr. Walter Carr, Master of the Haberdashers' Company.

The MASTER, proposing the health of "His Majesty's Ministers," said that when the medical history of the present day came to be written the development of the public health service would be reckoned as perhaps its finest achievement. No people had more reason to be grateful than the British for the excellence of their medical service, supported as it was by a sympathetic and helpful Government department. Turning to the society he represented, the Master claimed for the Apothecaries that they had always been to the fore in the art of healing; indeed, shortly after the society received its charter its members won their spurs by their devotion during the great plague of London. To-day they were by no means content to live on their traditions. As one instance of fruitful action, he mentioned that at the suggestion of the British Medical Association the society had instituted a register of bio-physical assistants, which would go far to prevent an important treatment from being exploited by charlatans.

Mr. ARTHUR GREENWOOD, in the course of a response to the toast, said that he had presided over his department for six months only; therefore he could claim no credit for what had happened during the first nine years of its existence. He was glad to be the guest of the Society of Apothecaries, because this body, with its ancient history, had modernized itself so as to play a noteworthy part in current medicine. As one of the ordinary folk, he was most grateful to all who practised any form of the healing art. Notwithstanding the great advances of medicine in recent years, there still remained a vast amount of preventable suffering and mortality. The problem of public health went beyond all political and indeed all national frontiers. It was a world problem, and not a few of the difficulties with which the medical profession was faced to-day would be overcome only by co-operation with the organized profession in other countries. In days gone by, as a teacher, he had felt himself "up against" general social conditions of a depressing kind, which he could not control, and he did not doubt that the medical practitioner and the public health officer often felt the same. Mr. Greenwood said he believed that to-day, in matters of public health, this country was leading the world. It was the British Empire which had been the inspiring force in the Health Section of the League of Nations. If only a more general and comprehensive attack on the broad problems of public health could be made, and this nation become a healthy nation, he was sure that it would lead the world in intellectual and spiritual progress.

Sir GEORGE BUCHANAN, Senior Warden, proposed the health of "The Guests," to which brief replies were made by Mr. Justice HUMPHREYS, Sir HUMPHRY ROLLESTON, and Sir ANDREW BALFOUR.

Sir Andrew Balfour said that there could be little doubt that the physician sprang from the loins of the apothecary. Not so very long ago it was the custom in certain medical schools for the students to serve an apprenticeship in the chemist's place of business, where they learnt neatness, care, and cleanliness, and also the smell, and sometimes the taste, and incidentally the cost of drugs. All this was of great value in future professional practice. There were people to-day who proclaimed that the era of drugs had passed; that this was the golden age of vaccination and immunization and ultra-violet radiation and endocrine therapy. But at any rate in that branch of medicine with which he had a close acquaintance—namely, tropical medicine—many drugs, such as quinine, emetine, tryparsamide, and opium, were of the first importance in the treatment of disease, or, rather, in the treatment of the patient, for the Society of Apothecaries had always emphasized the necessity of treating the patient, not the disease.

Scotland.

Health of the School Child.

THE school medical officer of Midlothian and Peebles education authorities refers in his annual report to several matters bearing on the health of school children in this area. He suggests that excess of clothes is apt to make a child subject to colds, while tightness of the clothing restricts the movements of the growing chest. He draws attention to the undesirability of rubber shoes, which are often worn, and make the feet tender. Too many children have hair in a verminous condition, though definite improvement in this matter is noted. The condition was, generally speaking, confined to certain families, in the members of which it appeared to persist in spite of efforts of the medical and nursing staff to secure improvement. The summoning of negligent parents before the various school management committees on account of the condition of their children resulted, in many cases, in temporary improvement. Great difficulty was often experienced in getting the parents of so-called mentally defective children who, while not being institution cases, were yet unable to benefit properly from the education provided in ordinary schools, to consent to their transference to a special school. Parents were seldom willing to recognize mental defect unless this was so obvious that the child was really an institution case. It is regarded as unfortunate that the same term should be used to include the feeble-minded and also the imbecile and idiot. It is urged that if parents were more careful of children's teeth between the ages of 2 and 5, many mouths might be maintained in a comparatively healthy condition throughout school life, because in many cases much damage by decay had been done before the child started attendance at school.

A memorandum has been issued by the Department of Health for Scotland and the Scottish Education Department, dealing with school health administration as it will be affected under the Local Government (Scotland) Act

from May 15th next. It is stated that no field of public health work is more important than that of the school health service, which is responsible for the medical supervision of over 800,000 children, or one-sixth of the whole population of Scotland. The inculcation and establishment of hygienic habits during the nine or ten years spent at school will have a profound effect upon the habits and usefulness of these children when they become adults. The broad aims of school health administration are stated to be: to secure healthy growth and development and to prevent sickness among school children; to provide systematic medical examination and supervision during school life; to keep under observation all children found to be suffering from physical or mental defect; and to provide appropriate treatment for the children of necessitous parents, and secure that other parents have their children treated when necessary. For preventive work, provision is to be made for medical supervision of nutrition, hygiene of the school, control of infectious disease, and physical education of the children. For medical examination and supervision of the children, routine medical examination by age groups is recommended; also the re-examination of children found to be suffering from defects. The special forms of medical treatment which are likely to demand attention in addition to treatment of disease in general are: treatment of nutritional disorders; treatment of deformities by orthopaedic procedures; clinics for special types of defect; treatment of defective vision; treatment of defective teeth; operative treatment, such as that for enlarged tonsils and adenoids; and the general care of physically defective children attending special schools. In the case of mentally defective children, classification and supervision are required; also the care of mentally defective children in special schools; and, finally, the determination at the age of 16 whether future care and supervision are necessary.

Glasgow Western Infirmary.

At the annual meeting of Glasgow Western Infirmary, Colonel J. A. Boxburgh, who presided, said that both the ordinary and extraordinary incomes in 1929 were much the same as in the preceding year, while the expenditure was somewhat less. During the past year the Infirmary had treated a greater number of patients than in any year since its opening in 1874. The auxiliary hospitals which were worked in connexion with the Infirmary had proved most valuable. Thus the David Elder Infirmary at Govan had treated 600 of their convalescent patients, and the Lady Hozier Convalescent Home at Lanark had also been a valuable aid. The chairman adverted also, in some detail, to the question of road accidents in relation to Glasgow hospitals. He said that the Road Traffic Bill now before Parliament, which would make insurance of third-party risks compulsory, might render possible some arrangement to reimburse hospitals for their large outlays in connexion with motor accident cases. The difficulty of the problem was at present increased by the fact that many of the cases of accident did not belong to the area of the hospital to which the victims were brought. These accidents were very serious for the smaller hospitals, but even in Glasgow they had in the last year cost the three large infirmaries over £10,000. The number of motor car accidents treated in the past year at the Western Infirmary alone had amounted to 222 indoor patients and 212 out-patients. Motor omnibus accidents had, in addition, accounted for forty-three indoor patients and fifty-four out-patients; and tramcar accidents for thirty-six indoor and seventy-one out-patients. At the same meeting it was intimated that Sir Henry and Lady Meehan had donated £5,000 for the purchase of radium for the Western Infirmary. Lord Provost Kelly afterwards addressed the nurses, to whom the medals and prizes gained during the year were then distributed by Lady Stirling Maxwell.

New Cripple Home in Edinburgh.

The Edinburgh Cripple and Invalid Children's Aid Society held its annual meeting on December 13th, 1929, when opportunity was taken to visit the new home situated at Challenger Lodge, Boswall Road, Edinburgh. Mr. G. F. Henderson, chairman of the board of managers, presided, and said that a munificent gift of £6,000 from a friend of the society had enabled them to secure the present house in place of the homes at Nellfield and Viewforth, which had been latterly regarded as inadequate. He referred to the work of the after-care committee, which had secured a teacher of arts and crafts, because one of their great problems had been to find work for those who remained cripples when they were adults. Lord Murray, in proposing the adoption of the report, said that they need not be alarmed about a deficit between income and expenditure, because he believed that subscriptions would satisfactorily increase. Mr. W. J. Stuart, honorary surgeon to the home, seconded the adoption of the report, and said that the idea of the orthopaedic hospital which was at present being erected at Fairmilehead started with this society. The scheme had met with the sympathy of the Lord Provost, and a committee which had subsequently been appointed had worked so hard under the chairmanship of Sir David Wallace that the scheme was now in process of taking visible shape. The question of after-care of cripples was a most important one, and upon it depended the whole success of what was done.

Greenock Auxiliary Hospital.

A new auxiliary hospital, designed to receive convalescent patients from Greenock Royal Infirmary, was opened at Larkfield on December 22nd, 1929, by Miss Rankin. Mr. D. S. Macpherson, chairman of directors of Greenock Royal Infirmary, presided, and said that the hospital was being opened free from debt, while seven beds in the public wards had already been endowed by gifts of £1,000 for each bed. Sir Donald MacAlister, Chancellor of Glasgow University, said that in providing for the convalescence of patients in fresh air and sunshine Greenock Royal Infirmary was giving a lead which he hoped other hospitals would follow. An important matter was that this hospital also provided for invalids who desired to be independent, though they could not afford to enter an expensive nursing home, and the need for people such as these was a very urgent one. The hospital has been built at a cost of £60,000, and consists of two public wards for convalescent patients of the Royal Infirmary, as well as a wing with rooms for twenty paying patients. The total accommodation is for forty beds.

Cremation in Edinburgh.

The first annual meeting of the members of the Edinburgh Crematorium, Limited, was held on December 27th, 1929. The secretary stated that since the crematorium had been opened on October 3rd, 1929, there had been nineteen cremations, which were now taking place at the rate of four or five per week. Eight of the nineteen cremations had been those of insured persons, and they made an appeal specially to the artisan classes, not merely on grounds of sanitation and public health, but also for the sake of economy. The cost of cremation in the case of an insured person was only £4, the total minimum charge being £4 10s., and the public were now coming to understand that they could economize in regard to funeral expenses if they adopted the system of cremation.

England and Wales.

Improvement of the Tuberculosis Service.

THE Joint Tuberculosis Council has issued a memorandum on the improvement of the tuberculosis service, in which it points out that the efficiency of this service varies widely in different districts, though backward areas are being improved by wise stimulation from headquarters; supervision should not be used so as to hamper individual initiative or to impede experimental methods. The chief factor in success is the personality and ability of tuberculosis officers and superintendents of sanatoriums, and therefore a remuneration sufficient to attract good officers is all-important. The council holds that it is better to have fewer and better paid officers with wider areas than a large number of poorly paid men and women of mediocre capacity. Rural areas with populations of 250,000 and urban areas of 350,000 can be managed by one whole-time

officer with adequate medical and clerical assistance, and would provide sufficient remuneration. The service should be graded so that those officers who had acted as assistants might become higher salaried, whole-time, consultant tuberculosis officers, or senior sanatorium superintendents. Superannuation schemes (the memorandum proceeds) should be generally adopted, and be so arranged that an officer shall not suffer by being transferred to another district. The tuberculosis officer and sanatorium superintendent should have at their disposal facilities for diagnosis, such as an x-ray outfit, and also for special forms of treatment, such as actinotherapy, and artificial pneumothorax. Each tuberculosis officer should have hospital beds. Dispensary and sanatorium officers should be clinicians first and foremost, but should have a public health outlook; facilities to attend post-graduate courses are of the highest importance. In certain circumstances, where the sanatorium belongs to the authority responsible for the district in which it is situate, it may be advantageous for the medical superintendent of a sanatorium to be responsible for the tuberculosis work in the vicinity of the institution as part of his whole-time duties. It is not intended that this should apply to sanatoriums other than those under the direct control of local authorities. The practitioner's sense of responsibility in the diagnosis, prevention, and treatment of tuberculosis must in no way be impaired, and it is the first duty of dispensary and sanatorium officers to ensure this. One of the most helpful qualifications for these officers is to have been themselves in private practice. In conclusion, the Joint Tuberculosis Council records its belief that any improvement in the tuberculosis service is closely bound up with the preliminary training of men entering this service, and with the education of medical students and general practitioners in tuberculosis.

Merseyside Hospitals Council.

On October 30th, 1928, the Liverpool Voluntary Hospitals Council, following conferences with the leaders of organized labour in the district, adopted a revised constitution in terms of which it changed its name to the Merseyside Hospitals Council, and gave direct representation to affiliated trade unions. It decided that all manual workers, irrespective of income, should be invited to take part in a contributory scheme entitling them to hospital privileges at any of the associated institutions, but that for clerical workers certain income limits should apply; later on, however, it will consider the question of incorporating salaried workers above these income limits. In the report for the year 1928 the council draws attention to the success that has already attended the scheme. The number of contributors increased from 58,200 at the end of 1927 to 153,142 at the end of 1928, and the income from £28,860 to £63,574. By November, 1929, more than 210,000 employees, in about 3,000 separate firms and establishments, were individually contributing an average of 7s. 6d. per annum to the council's fund. Including wives and children, the scheme is thus providing an opportunity for more than half a million of the Merseyside population to be independent of charity for covering the cost of their maintenance at the local hospitals. The council refers with pride to the civic sense of the Merseyside people, and pays special tribute to the employers, who not only collect contributions through their pay offices, but generously add a subscription equal to one-third of their employees' contributions, sending their money at regular intervals to the central office. As part of the scheme the council is developing a convalescent and after-care service, and an ambulance service. Twenty-five institutions in Liverpool, Birkenhead, Wallasey, and Waterloo have accepted the council's scheme, and on the nomination of the council the associated hospitals have accepted representatives of the contributors and of organized labour on their boards of management.

Epidemic Sore Throat at Brighton.

During December last a large number of persons in part of Brighton and Hove suffered from sore throats of a more serious type than usual at this season, and eventually a statement was issued on January 5th by Dr. Rutherford Cramb, deputy medical officer of health for Brighton, and Dr. A. Griffith, medical officer of health for Hove. It was explained therein that inquiries had been made into all the probable causes, including the milk supply, and one dairy in particular had been indicated as being associated with the infection. Further investigation resulted in one farm being implicated, and the supply of milk from it was accordingly stopped from December 28th. So far as could be ascertained, no fresh cases had been reported during last week, except in families already affected, and it was concluded, therefore, that residents and visitors need have no fear of further infection. No official notification has yet been issued as to the bacterial nature of the outbreak, but it is believed to have been chiefly of a streptococcal origin.

British Social Hygiene Council.

The British Social Hygiene Council has been urging upon the London County Council that propaganda work in connexion with venereal diseases may be continued under the changed financial conditions whereby grants are no longer paid directly by the Ministry. In order to continue its national services and remain in a position to supply local authorities with what they need for their local campaigns, the British Social Hygiene Council states that £10,000 a year is required, and on the basis of this figure a contribution at the rate of 5s. a thousand of population, which for London represents about £1,120, is asked. The London County Council has decided to make a grant of this amount to the central funds of this body, towards which sum the L.C.C. will receive in its block grants about £670 a year, equal to 3s. a thousand of population. Consideration of a grant to be made to the same body for local services in London has been postponed.

Ireland.

Legislation for Clean Milk Supply.

In the course of a lecture delivered recently, Professor Grimes of the Department of Dairy Bacteriology at University College, Cork, said that milk was the best single food, because it contained all the essentials of a balanced diet. The fat standard in milk was most important. The law at present was that milk containing less than 3 per cent. of milk-fat was not genuine by reason of the abstraction therefrom of fat, or the addition thereto of water. The weakness of a fixed standard was that the percentage of butter-fat varied throughout the year. He saw no reason why the defence that the milk was sold as it came from the cow should be considered valid. Many cities in the United States insisted on a standard of 3.25 per cent. butter-fat and over, and they got it. A definite standard would increase cow-testing and make the milk suppliers keep only cows whose milk contained a satisfactory percentage of butter-fat. The consumer paid for milk containing a minimum of 3 per cent. butter-fat, and where bottled milk was sold containing a higher percentage—say, 3.5 per cent.—the fact should be stated on the label; the customer should be prepared to pay a higher price for it, and it should be a punishable offence if the milk did not contain the percentage of butter-fat stated on the label. It was interesting to note that, legally, there was stricter control over milk used for manufacture into dairy products than over milk used for human consumption. That was a condition of things that could not be remedied too soon. Dirty milk, from the standpoint of public health, must be considered potentially dangerous; yet "clean" milk was by no means necessarily safe milk: if infected with disease-producing bacteria it was more likely to preserve and carry infection, since it kept fresh longer, which meant that the disease-producing bacteria had comparatively little competition, and that the usual souring, which was detrimental to the disease-producing bacteria, did not occur. Pasteurization would not make dirty milk good, but it made clean milk safe. When legislation on the subject of milk was being enacted it was to be hoped that it would have the support of the consumer; but just as the housewife recognized various grades of butter, tea, meat, etc., so she would recognize the value of graded milk, and would be willing to pay for the better article. That would give a satisfactory incentive to the producer to produce Grade A milk. To prevent the danger of food poisoning through

ice-cream it was necessary that there should be power to fix bacteriological standards with which it would have to comply, and also to ensure that it contained a certain minimum percentage of butter-fat. In conclusion, Professor Grimes suggested that the milk supply to cities should be regarded as a "public utility," just as was the water supply. There was a direct responsibility on the Government and local authorities to prevent community injury through the use of milk. While recognizing this, it was necessary that the legislation should be so framed that every encouragement was given to increase both the milk supply and its consumption. Education was needed with legislation, for the good will of the producer was necessary to give the consumer a satisfactory milk supply. Dr. Brian Crichton said that, as one who worked solely among children, the question of cleanliness to him came before that of butter-fat. Tuberculosis, diphtheria, and vomiting were produced through dirty milk, and led to the deaths of hundreds of children. The time had come when the Government should at least try to ensure that the child should be supplied with clean milk from the cow. The bulk of the milk sold in Dublin was not fit for a child to drink, and milk was the only food that a child under 12 months old could use. It was now everybody's business to see that the proposed bill was passed into law.

The Local Government Department and Medical Appointments.

At the last meeting of the Monaghan County Council it was announced that a sealed order had been received from the Department of Local Government and Public Health fixing the salary of the doctor to be appointed as county medical officer of health and schools medical officer at £800, with £200 travelling allowances. The Minister also requested the Local Appointments Commission to recommend a person for the office. The county council had fixed the salary at £700, with £100 travelling allowances. The Department has also transmitted a sealed order to Limerick County Council to the effect that the Appointments Commissioners had been instructed to fill the position of county medical officer of health at a salary of £800 a year, with £200 a year travelling expenses. It has referred the appointment of a medical officer of Macroom Cottage Hospital to the Local Appointments Commissioners. The South Cork Board of Public Assistance had already appointed Dr. Kelleher, a pensioned medical officer, to a position at £700 a year. The Department also wrote refusing to sanction the Board's action in transferring Dr. Cagney, dispensary officer, to the post of visiting physician to the County Hospital, on the grounds that it was not advisable to transfer dispensary officers to such positions. The Board decided to ask the Department to reconsider its decision.

Decrease of Tuberculosis Mortality in Ireland.

At a meeting of the National Association of Insurance Committees, held recently in Dublin, it was stated that when national insurance was introduced into Ireland they were in the sorry plight that one in every seven persons was dying of tuberculosis. After some years' work they could now pride themselves on the fact that the number had been reduced to one in eleven.

India.

Economic Considerations in Public Health.

A PERTINENT question was put by Mr. G. Bransby Williams, late chief engineer to the Bengal Public Health Department, in an address which he delivered to the Rotary Club of Calcutta last June. Is, he asked, expenditure on public health productive of wealth, or will it in the end lead to over-population and death from starvation? Some people in India, he added, seemed to hold that such dangers were likely, for the expenditure by certain Government authorities in India on sanitation, water supply, and anti-malarial measures was ridiculously small; such indifference in these matters would not, he added, be tolerated even in a remote agricultural district in England. According to Mr. Williams, the death rate in Calcutta has increased by 50 per cent. in the last twelve years, while the drainage system has been allowed to silt up and no serious attempt has been made to maintain it. In the case of Bombay, he asserts, half a city of one million inhabitants is undrained, while Howrah, a town of 200,000 inhabitants, is without any form of sanitation, has filthy streets, and its water supply is quite inadequate. He believes that millions of lives could be saved annually, the efficiency of Indian workers be remarkably increased, and the amount of the suffering caused by disease be substantially diminished if only the Indian Government would undertake a series of public works, of which the cost would be defrayed by a loan, and the annual charges for capital and maintenance be met by a levy upon the owners of the land, who would benefit by the improvement. To obtain evidence of the practical value of this proposition Mr. Bransby Williams suggests that a site in a notoriously unhealthy and impoverished district might be selected; public health and irrigation work would be undertaken, epidemic diseases be eradicated so far as possible, and the area of land under cultivation extended. If such a policy was adopted he believes that the annual value of imports per head of population of India might be increased many-fold from its present miserable twelve shillings. He maintains that there would be a far greater financial return from two hundred million pounds spent thus in India than would be the case in England; the whole condition of the land would be transformed. Girding against the "obsession" as to the poverty of India and the difficulty of raising money for public works, he insists that the difference between productive and unproductive expenditure seems to have been ignored. He gives illustrations of the effect of such conditions on health, and states that the expectation of life of the Indian child at birth is about half that of the British child. He estimates the total annual cost of preventible diseases as being about two thousand million pounds, and bases upon this his argument that expenditure on public health is really a wise economy and a sound commercial undertaking.

The Medical Department of the Great Indian Peninsula Railway.

Railways have long been recognized as pioneers of civilization, but it is forgotten sometimes that in some countries, such as India, they make a not inconsiderable contribution to the promotion of health and the prevention of disease. An illustration of this is afforded by the annual report of the medical department of the Great Indian Peninsula Railway for 1928–29. This railway system employs more than 120,000 persons, and Mr. R. J. L. Sladen, F.R.C.S., the principal medical and health officer, mentions in the report that there are in his department eleven district medical officers, two assistant medical officers, and thirty-two assistant and subassistant surgeons. In addition, there is a "health staff," which since April 1st has consisted of seven "health assistants" and about forty sanitary inspectors. There are eight district hospitals, with a total of 181 beds, and in the year under review no fewer than 3,500 operations were performed. Mr. Sladen reports that there has been a marked fall in the incidence of malaria. This is attributed to the comparative healthiness of the year, greater care taken in diagnosis and registration, and the prosecution of antimalarial measures. At the same time it is admitted that the incidence of malaria varies greatly from year to year. As regards antimalarial campaigns, the company's medical officers appear to deprecate the adoption of large engineering schemes of doubtful advantage and entailing heavy expense. They are convinced of the utility of filling in low-lying lands, improving drainage, careful and continued search for the breeding places of anopheline mosquitos, and systematic treatment with crude oil. The organization of malarial surveys is developing. During the year 88 cases of cholera were reported, with a death rate of 34.09 per cent.; evidence of the efficiency of the precautions taken is afforded by the fact that the intrusion of infected pilgrims from the Kurukshetra Fair at Muttra did not occasion an epidemic among the railway staff. Only 25 cases of plague were reported, with a case mortality of 36 per cent. Although more than 63,000,000 passengers were carried, only sixteen fatal accidents occurred; an increase in non-fatal accidents

among railway servants is attributed to greater care in reporting. Thirty-five more deaths from accident than in the previous year among "other persons" were due, apparently, to more trains run at a higher speed catching trespassers unawares. In view of the increasingly prevalent use of electricity on the railway, Mr. Sladen recommends that special training should be given in Schafer's method of artificial respiration; that suitable equipment should be maintained in all power houses and substations; and that all electrical accidents should be specially investigated by an expert. He emphasizes the fact that in practically all cases of electrical shock there is a considerable interval between the onset of apparent and the moment of real death.

European Mental Hospital, Ranchi.

Europeans and Americans suffering from mental disorder are eligible for admission to the European Mental Hospital at Ranchi in the province of Bihar and Orissa; in addition, persons born in the British dominions and colonies, or their descendants, whether purely white or of mixed blood, are admissible if they are European as regards habits. This institution can accommodate 102 male and 56 female patients. In his annual report for 1928, the medical superintendent, Lieut.-Colonel Owen Berkeley-Hill, I.M.S., comments on the advantages gained by the discontinuance during the year under review of the rigorous segregation of the patients according to sex. Certain changes in the nomenclature of the wards and cottages were made, the names of leading benefactors to psychiatry being introduced with a view to enabling the patients and staff to keep in mind the debt of gratitude due to those who have rendered the treatment of mental disorder increasingly more hopeful. There has been a marked improvement in the number of voluntary patients admitted—one sign of the growing popularity of this hospital; rather more than half these patients come from Bengal, and one-quarter from the United Provinces. There was a marked decrease during 1928 in the daily average of the sick treated in the dispensary as compared with the previous year. Systematic attention is paid to the correction of bad habits, and a scheme has been devised for several members of the staff to co-operate in helping each patient in this respect. The hospital cinema is also described as having a therapeutic value. The staff of the institution are encouraged to compete from time to time in "research essays" on topics suggested by the medical superintendent and necessitating recourse to the valuable scientific library possessed by the hospital. Special steps are taken as regards the after-care of discharged patients, a follow-up-letter system being employed, while in Calcutta, the Bengal Presidency Council of Women, and Toc H. have continued to pay periodical visits and report on the home conditions of these patients.

Correspondence.

GASTRIC AND DUODENAL ULCERS.

SIR,—When preparing the report on "pyloric ulcers" I expected that the question asked by Lord Moynihan (January 4th, p. 40) as to what exactly is meant by pyloric ulcers would be raised soon after the publication of this report. I must leave the surgeons to settle this question, but as a collator I consider that I was bound to take verbatim the answers given by the various surgeons to Question 7 as to the position of the ulcers. As the ulcers questioned by Lord Moynihan were described as "pyloric ulcers" or "at the pylorus," I was compelled to report on them as such, although I should have much preferred the two groupings of duodenal and gastric ulcers.

As a golfer, though I regretfully own to a very poor handicap, I appreciate the reference in your leading article on December 7th last to the establishment of a "bogey for the upper abdominal course." I do not know what Lord Moynihan's golfing handicap actually is, but if your golfing simile is to be applied to the surgeon's art, then Lord Moynihan's position would be at least the equivalent of that of Bobby Jones.—I am, etc.,

Limpsfield, Jan. 4th. ARTHUR P. LUFF.

A NATIONAL MATERNITY SERVICE.

SIR,—In the very kind review[1] of my recent book on the *Causes and Prevention of Maternal Mortality*, your reviewer points out that the ideal service I suggest is very similar to that presented in the recent Memorandum of the British Medical Association. I am naturally very gratified to think that my views have received such valuable confirmation. There is, however, one respect in which my "ideal service" differs materially from the scheme presented in the Memorandum, and that is in relation to ante-natal care and diagnosis.

It seems to me that "the efficient ante-natal care" which the British Medical Association scheme provides is somewhat too haphazard and not wholly sufficient. I think that the more the care of the normal woman in labour is entrusted to midwives, the greater is the necessity for ante-natal care and diagnosis. Further, while I regard medical assistance during normal labour as non-essential, and as possibly prejudicial to the patient's interests, I regard medical care and diagnosis during pregnancy as the great safeguard of her present and future well-being. This being so, I think that a satisfactory scheme should recognize the following: (1) The primary and absolute *responsibility* of a medical practitioner for ante-natal care and diagnosis. (2) The possible delegation of such care in minor matters to the selected midwife, at the option of the practitioner concerned. (3) The necessity for more frequent medical visits, and for close supervision by the practitioner or by the midwife, especially during the later months of pregnancy.

Whether such alterations in the present scheme are possible is another matter. Here I only draw attention to the fact that they are points which, in my book, I have regarded as essential, and which I think should form a part of any ideal service.—I am, etc.,

Christchurch, N.Z., Dec. 2nd, 1929. HENRY JELLETT.

CHILD GUIDANCE CLINICS.

SIR,—I was very much interested in the reply of Dr. Burke and Dr. Miller (January 4th, p. 45) to my letter published on December 28th, 1929 (p. 1219). I have great admiration for the work conducted by them at the Jewish Children's Clinic, but I think it is unfortunate that they should take up the attitude that a clinic for nervous or difficult children should preferably be kept apart from a general hospital. This, together with an implication that they mention—namely, that medical students cannot be trained in child mental hygiene—is precisely the opposite view to that which one would like the medical profession to adopt. My complaint was not of independent clinics (and not at all of existing ones), so much as of the indifference of general hospitals; but Drs. Burke and Miller's remarks force me into a defence of the latter.

Drs. Burke and Miller's advocacy of an entirely independent clinic seems to be based on four grounds: (1) that the almoner's office of a general hospital works on lines irreconcilable with a children's psychopathic clinic; (2) that the expense is beyond the capacity of a voluntary hospital; (3) that the necessary elasticity of method is impossible in a general hospital; and (4) that child mental hygiene is too difficult a problem for the student to tackle.

The first two objections already have a practical answer. There is a specially trained social worker already appointed at Guy's, at University College Hospital, and, I believe, at one or two other general hospitals, part of whose function is to deal with nervous children attending the psychiatric clinic. The governors of these hospitals have evidently thought the expense worth while even in these days of great financial anxiety. It has been found possible at Guy's for the psychiatric social worker to work in conjunction with the almoner's department, and no difficulty exists in this direction.

As to the assertion that it is impractical or unwise to train medical students in such matters, it is impossible to emphasize too strongly the reactionary nature of such a suggestion. It is only recently by great efforts that psychological medicine has been brought more closely into touch with general medicine—the *rapport* is not yet by any

[1] *British Medical Journal*, September 21st, 1929, p. 542.

means close enough. Psychiatry has too long been confined to asylums, and erected into something apart, at which the general practitioner—to the great loss of the community and himself also—held up his hands in aversion and sometimes even derision. Now Drs. Burke and Miller would try to perpetuate this error in medical education by making an esoteric mystery of what is one of the most interesting branches of psychological medicine, and certainly the most practically fruitful branch. If medical students are to be taught, as they are in fact already taught, about the mental problems of adult life, it is difficult to see any justification for refusing them similar instruction in the case of children.

It seems to me that a knowledge of elementary social problems is no more to be spurned in dealing with adults than in dealing with children. The general practitioner, into whom most medical students fortunately still develop, is precisely the person who is going to have the knowledge of the social problems of his patient, which is likely to be an adequate safeguard against that superficiality of outlook which Drs. Burke and Miller seem so fearfully to apprehend.

The statement that "the organization of the out-patient department and of the almoner's office of general hospitals is not, as yet, equipped for dealing with problems of this breadth" is already not wholly true in fact, and in any case is the very worst reason for refusing to countenance development along these lines in general hospitals as a whole.—I am, etc.,

London, W.1, Jan. 4th. R. D. GILLESPIE.

THE CONDUCT OF INFANT WELFARE CENTRES.

SIR,—In the *Journal* of December 28th, 1929 (p. 1186), Professor Leonard Findlay, lecturing on paediatrics to the Belgrade Faculty of Medicine and Medical Association, is reported to have said: (1) "I can picture no more demoralizing sphere of work for one's medical outlook than to be condemned to do nothing but supervise healthy infants and direct their feeding"; and (2) "Children from 1 to 5 years are at present not provided for." Dr. Findlay seems to hold the view that the only duties of medical officers at child welfare centres, to whom I suppose he refers, are the supervision of healthy infants and directing their feeding. I should like, therefore, to give some idea of the work done at these centres and the routine generally adopted.

The babies are brought when they are about 3 weeks old; the family history is taken; they are weighed each time they come; and any collateral information bearing on each case is obtained. All babies are seen by the medical officer and carefully examined at their first visit, and a strict record is kept of all particulars; their diet is discussed, special stress being laid on the great importance of breast-feeding. The mother is supplied, if necessary, with printed instructions how to promote or increase the supply of milk, and advised as to the number and duration of feeds; further advice is given on clothing, bathing, ventilation, exercise, and all desirable hygienic necessities. If breast-feeding is not satisfactory, the mother comes to the centre for three or more "test feeds"—namely, weighing the baby before and after each feed; should the supply be insufficient an amount of modified cow's milk is ordered to be given immediately after each breast-feed, so that the total amount will produce 45 to 50 calories per pound weight per day. If breast-feeding is impossible written instructions are supplied to the mother how to feed the baby on modified cow's milk.

The mother brings the baby to the centre once a week; if all is not going well she sees the medical officer. This goes on at lengthening intervals during the first year. From the first to the fifth year (for which Professor Findlay says no provision is made) the child is brought to the centre once a month; if any evidence of illness or disease is apparent the case is referred to the private medical attendant or to a hospital. For minor ailments simple remedies are prescribed. We frequently meet with cases of malnutrition, marasmus, and sometimes coeliac disease, where dietetic treatment is sufficient.

We have never posed as specialists, although Professor Findlay refers to us as "pseudo-specialists." I have on several occasions interviewed deputations from America, Sweden, Japan, South Africa, and other places at our centres, and they have invariably expressed keen appreciation of our methods. I have had communications from them when they returned to their own countries, in which they have expressed their gratitude for what they learned from us. There is, I regret to say, among some members of our profession, a feeling of hostility to our work, for which I see no reason. We are most anxious to work amicably with every member of our profession.—I am, etc.,

J. FINCH HAINES, M.D., M.Ch., M.A.O.,
One of the Medical Officers to St. Pancras and East Islington Welfare Centres.

London, N.W.6, Dec. 29th, 1929.

THE GENESIS OF CANCER.

SIR,—In furtherance of the effort of the British Medical Association to make a survey of factors relating to the incidence of cancer, I venture to send the following notes. It is possible that they may lend precision to the description of the agents responsible for the local hyperplasia which, if prolonged, may eventuate in malignancy.

This local proliferation, in response to the long application of certain substances to living cells, is regarded as the first stage of cancer development. During its progress, and by reason of the vitiating action of the applied agent, the cells change their metabolic and respiratory methods and lose their histological and functional differentiation. After several generations in this form the type is established and the cells will tend to breed true unless a modicum of tissue fluid, now their sole nutritional requirement, is denied to them. They are transformed, as Cheatle describes, in the breast, into cancer cells, although not yet introduced through the connective tissue barrier, be it elastica or corium.

This introduction forms the second stage, and is effected by trauma, incomplete operation, rupture of duct or cyst, and other mechanical disjunctions, or by direct extension. In the third stage—the stage of perpetuation—the altered cells grow and multiply, to the detriment of the host, in any situation where tissue fluid is available. A discussion of the second and third stage is outwith the scope of this letter.

On what does the initial hyperplasia, or first stage, depend? This question is usually answered by the phrase "chronic irritation," but the vagueness of the term deprives it of any useful scientific meaning, and necessitates close inquiry into the grouping of the carcinogenetic substances. The oils, long associated with the soothing of injury, and the tars, employed in the cure of irritative skin lesions, would not fall naturally into an irritant group. Acids and alkalis, of sufficient strength to provoke a reaction, are definite irritants. Nevertheless we find, dealing for the moment with experimental and occupational cancers, that the carcinogenetic agents lie among the apparently bland and non-irritating substances, while the acids and alkalis, though they may produce erythema, oedema, vesication, and even ulceration when applied in sufficient strength over a long period, will never by their own action produce a true hyperplasia, papillomatosis, or cancer. Such soluble toxic substances are rapidly diluted by the local outpouring of fluid, carried in the circulation and eliminated by the kidneys or other route, as Lewis has shown with great experimental exactitude. Toxic substances, which are insoluble in the tissue fluids but are also viscous, and so able to permeate through the cellular strata, evoke an entirely different and fundamentally important reaction.

Substances which exhibit this physico-chemical complex of insolubility, viscosity, and toxicity (we will call them potent substances) will, on prolonged contact with living cells, lead to one of three results: (1) Hyperplasia may develop, by which the ingress of the potent substance is prevented, and, by *proliferation and desquamation*, the noxious agent is removed in adhesion to the desquamated cell. (2) No hyperplastic response may take place. The potent substance entering the lymph channels and capillaries ultimately reaches the liver. If the quantity of the substance and the degree of toxicity be sufficient death ensues, usually with marked cachexia. (3) A subeffective hyperplasia may be exhibited in which the slow proliferative effort is inadequate. A certain quantity of the potent

substance is thrown off. Some reaches the lymphatics, which become blocked, and papillomatosis develops. Some also reaches the liver, and we will see a local hyperplasia concurrent with chronic toxic absorption. In the possession of the three essential properties lies the only specificity among carcinogenetic agents.

Where do we see the physico-chemical cause at work? In my opinion it is operative in all cases, except in the very small and special groups of the malignant blastoma—for example, renal—of early childhood, and the melano-carcinoma of naevus cell origin, which Nicholson and Dawson have so admirably explained. Among the enormous number of individuals who are engaged in chemical manufacture, or who use strong chemicals in their work, there is no incidence of occupational cancers, except in the comparatively small group of those who are exposed, directly or indirectly, to the action of potent substances, such as tar, paraffin, and shale oil workers, mule-spinners, etc. In the non-occupational cancers it is my belief that in causative relation with all precancerous proliferative states will be found a potent substance, as, for example, effete retained sebaceous oil, the semi-inspissated secretion of the breast, the muco-purulent discharge of a uterine endocervicitis, the slimy mucus of stomach or large bowel, the fat-soluble poisons in partially burned skin, stale extravasated blood, the myxomatous degeneration of a simple tumour, or the tobacco oil which percolates through a porous pipe. The action of these substances is known to be intensified by acids, while they are dissolved or emulsified in alkalis. On this fact may depend the immunity of the small bowel from malignancy and the increase of cancer as age advances and the blood and tissue alkalinity slightly decline.

It is impossible within the bounds of a letter to discuss the full implications of this view or to make adequate acknowledgement to all the workers on whose results these deductions are based. It is of great interest to consider the action of the fibrin, lecithin, and cholesterin of extravasated blood which correlates the process of local hyperplasia, and probably of sarcoma, with normal tissue repair and early embryonic development. Of importance, also, is the increase of potassium in the slightly vitiated cell; by this means imbibition of fluid is facilitated and, very probably, radium sensitivity is determined. At present my purpose is to direct attention to the composition of the potent substances, and to suggest that they may be borne in mind by some of those who are taking part in the admirable inquiry of the Association.—I am, etc.,

Edinburgh, Dec. 26th, 1929. J. J. M. SAAW.

MENTAL DISORDER AND INTESTINAL SEPSIS.

SIR,—The much-discussed relationship between mental disease and intestinal sepsis has suggested to me that the following illustrative case might be worth recording.

That intestinal auto-intoxication is one of the causes contributing to and resulting from melancholia, in cases where there is a family history of insanity of that type, is well known, and has been repeatedly demonstrated clinically, but that this condition *per se* can apparently be responsible for an attack of melancholia in a case where no family history of insanity exists is, I think, illustrated by the following case.

A widow, aged 55, gradually developed symptoms characteristic of a recent melancholia. She was hypochondriacal, mildly delusional (her delusions being of the visceral type), and she repeated words again and again in a parrot-like, incoherent manner. She had the typical facies of the melancholic, and took no interest in her surroundings or friends. No focus of chronic or other infection in the mouth, throat, nose, sinuses, appendix, or uterus could be found, but a very definite history was given of chronic constipation, which had become aggravated recently. The patient was sent to a home, and placed under a suitable regime for her mental condition. The lower bowel was thoroughly and regularly washed out, and for over a week faecal concretions like marbles came away, some of which were encapsulated in mucoid material. Occasionally they were tinged with blood, probably due to slight ulceration of the intestinal mucosa by the scybalae. Intestinal tonics were administered, and a suitable diet prescribed. Under this treatment the patient's mental symptoms entirely subsided within fourteen days. (They had been continuous previously for three months.) She ate and slept well, enjoyed exercise and company, and put on weight.

The interesting feature of the case, to my mind, is the rapid clearing up of the mental symptoms, which have not returned a month afterwards. I doubt whether, if there had been a family history of melancholia, the elimination of the toxic condition would have been followed by the disappearance of the mental symptoms, but it would appear possible, at any rate from this case, that a mental condition based solely on an intestinal auto-intoxication in an individual free from any family taint of insanity will entirely clear up by thoroughly eliminating this condition.—I am, etc.,

C. JOYNER.

Torquay, Dec. 21st, 1929.

"TENNIS ELBOW."

SIR,—The correspondence in your columns on "tennis elbow" has emphasized the obvious point that this disability, which can only be defined as trouble in the elbow of one who uses a racket, may be due to any condition from a fracture to a Charcot's joint. But one who has personally suffered from a condition has both the stimulus and the opportunity for observation of a kind that is impossible from a purely objective view-point, and I have my own experience of a kind of injury that is common at tournaments, though rare in Harley Street because of a tendency to get well of itself. I have acquired, in the course of a liberal athletic education, both a ligamentous strain and an acute traumatic synovitis of the elbow, as well as torn muscles, acute bursitis, and acute periostitis elsewhere. (In all these I think sepsis can be excluded as a factor, since the cause was obvious, and the recovery complete without removal of either teeth or colon.) But my only tennis elbow was different from any of these, and the conclusions to which I came while sitting disconsolate in the players' stand were the following.

The injury is very like a riding sprain in its production and sensations; in both there is a tearing pain, produced by a sudden jerk on a contracted muscle. In the one this jerk is from the weight of the body flung against the gripping adductors, and in the other from the momentum of the ball transmitted through the racket on to the tense extensors of the wrist. In both the pain is confined to a definite spot just below the origin of the muscles concerned, and in both it becomes rapidly worse on continuing their use.

The actual damage is a tear of the aponeurosis of the extensor carpi radialis longus, the mechanism of which can be roughly imitated by gluing a strip of paper on top of a strip of thin leather, and then jerking the double strap so formed. The paper, being like the aponeurosis, almost inextensible, will split across; while the leather, like the muscle, stretches under the strain.

This explanation seems to me to fit *this particular injury* in many ways: (1) The pain only occurs where there is an aponeurotic covering to the muscle; (2) though one feels a distinct tear there is no effusion of blood, as the aponeurosis is an avascular structure: (3) healing is very slow for the same reason; (4) any use of the elbow-joint not involving the wrist extensor is quite painless; (5) any strain on the ligaments of the joint is also painless; (6) the maximum of pain is produced in the same way as the original injury—by a jerk on the contracted extensors.

It is common ground, again at tournaments, that the injury belongs particularly to the backhand shot. To explain this I would state a principle, which to my long-suffering friends is known as "Browne's law," that at the moment of striking with any instrument the wrist should be in full extension, the position of greatest grip. This is the real meaning of the advice to keep the head of the racket up, which is as universally given to novices as it is disregarded by experts. Now in the forehand shot (let me implore certain contributors not to use forearm in the sense of forehand) the thrust of the stroke is against the palm, and is largely taken by the ligaments of the wrist, if this is in the proper position, as its tendency is to extend a joint already fully extended. Incidentally, if Dr. Warden will study the production of two

of the best forehand drives ever known—those of Johnston and Harada—he will find that in them the forearm is locked in full supination, as well as the wrist in full extension, against the impact of the ball. In the backhand shot, however, the thrust is against the thumb, and tends to flex the wrist, so producing at each impact a jerk on the extensors which alone resist it.

As to the part played by bad shots, it does not require any very recondite calculations of ballistic centres to ascertain that it is the mishit ball that jars the wrist; and quite possibly an imperfect contraction of the muscles renders them more liable to injury of this or any other kind.

As I am only too well aware of the breach of sporting etiquette which it is to mention mechanics or anatomy in discussing a game, I feel I must apologize for the converse sin of touching on the technique of a game in a medical journal.—I am, etc.,

London, W.1, Jan. 6th. DENIS BROWNE.

SIR,—The correspondence on this subject has been so comprehensive that one is tempted to "leave it at that," were it not that a treatment of sovereign utility has not been mentioned in your columns. I refer to the oldest form of electricity used in medicine, yet one, in this country at any rate, much neglected—static electricity. The form of it which is of great use in "tennis elbow" (or "tennis arm," Dr. A. A. Warden terms it, and this coincides with my own experience) is the static wave current. The effects of this current are chiefly or entirely mechanical; the current causes tissue contractions—the coarser ones which can be seen, and finer contractions within the tissues—perhaps 120 contractions to the minute. It is not difficult to understand why the application of this current to the elbow should improve the condition and remove the congestion and exudation, which are the invariable concomitants of all forms of tennis elbow.

While agreeing with Mr. Paul Bernard Roth that "tennis elbow is due to several pathological conditions," I am of opinion that there is in all, or most of these conditions, one common factor—namely, a serous effusion, possibly, an inflammatory congestion of the synovial membrane, and an inflammatory exudation, the "coagulable lymph" of John Hunter. Erichsen pointed out the theory of treatment many years ago. "If," said he, "the disease progress favourably, these products are completely absorbed." In the static wave current we have an agent which will, by its mechanical action, disperse that congestion and so improve the circulation that these products are readily absorbed; and by hastening the absorption of morbid products it compels the disease "to progress favourably."

Turrell of Oxford, in speaking of this form of electricity, used by him for a sprained ankle, in which the pathological conditions are not altogether dissimilar, said, "I am not exaggerating when I state that during the football season I daily see examples of the immediate and lasting benefits of the static wave current in this class of case."—I am, etc.,

London, W.1, Jan 6th. F. HOWARD HUMPHRIS, M.D.

SIR,—May I offer a suggestion as to the treatment of 'tennis elbow" in those cases which are in the primary stage? The patient declines to stop his game; he is not quite bad enough. Yet every jerk given the elbow increases the mischief. Why not, then, induce him to wear an angular metal splint, braced by the usual armlets, with buckles above and below the joint, the whole fixed at a wide but varying angle, adjusted by a screw? Such a splint may at first feel cramping and cumbrous, but the player will probably soon accommodate his action to the fixation, as so many men have done in other injuries. If such a splint was well made and comfortably adjusted, it might, theoretically, to take the jerk, and to prevent the drag and strain on the joint, which is the principal factor in producing tennis elbow. At any rate, such a splint is worth trying, when the only alternative is complete cessation from play.—I am, etc.,

T. M. CORKER, Major-General.

Junior United Services Club, Jan. 6th.

HEALING OF THE TONSIL FOSSA AFTER TONSILLECTOMY.

SIR,—A contributor to your issue of December 28th, 1929 (p. 1196), assumes as a criterion of tonsil infectivity, among other things, "the presence of any tissue in the tonsil beds after tonsillectomy." He is perpetuating a common fallacy, that besets many physicians, that any residuum remaining in the tonsil fossa after complete enucleation is tonsillar tissue. In so doing he disregards the manner in which the healing occurs in the raw area left after removal of the tonsil. This heals up in a manner similar to any other uncovered wound—namely, by the formation of granulation tissue, which then becomes epithelized over, a process that is complete from the fourteenth to the twenty-first day. The formation of this granulation tissue interests the physician from two aspects.

1. One of the characteristics of this granulation tissue is its ability to bleed easily on the mildest of trauma, and it is this that gives rise to the majority of cases of secondary haemorrhage after tonsillectomy. A cough, bolting of solid food, or any such trauma is liable to dislodge a portion of the fragile granulation tissue, and produce a haemorrhage that is sudden in onset, spontaneous in cessation, and severe in amount. The surprising thing is that secondary haemorrhage is as rare as it is. Silver nitrate stick applied locally will always control this bleeding.

2. But this tissue formation has another significance. On occasion it is apt to be exuberant in bulk, and present as a fleshy mass in the tonsillar fossa. It is then by the uninitiated mistaken for a piece of tonsil left behind at operation, and its removal by further operation is advised. This excrescence should be removed, as exuberant granulations elsewhere, by the caustic stick, and not the scalpel. As I have had occasion to state elsewhere (*Clinical Journal*), there are physicians who are always of the opinion that unless tonsillectomy is performed by their own surgeon, the tonsil has never been satisfactorily extirpated. When they observe this mass of residual granulation tissue they invariably inform the patient, or the latter's parents, that the operation has been imperfectly performed, and has to be done again. They dwell with unwonted enthusiasm on the evils that will result from the retention of these pernicious "tonsil" remains. It is a matter calling for the display of much tact to disabuse the mind of such a patient and to reassure him that no further operation is called for. And all this is a result of ignorance of the normal pathology of the healing of the tonsil bed after tonsillectomy.—I am, etc.,

London, W.1, Dec. 28th, 1929. N. ASHERSON.

SECURITY OF TENURE IN PUBLIC POSTS.

SIR,—Readers of the correspondence on security of tenure in public posts will be interested to note your extract (December 28th, 1929, p. 1215) giving the considered opinion of the Royal Commission on the subject. The Commission's recommendation is satisfactory so far as it goes, but it does not directly protect the officer's pension, and therefore does not meet the view expressed in your leading article of March 9th, 1929 (p. 461), in which you stated:

"And certainly it will be necessary to secure changes in the Local Government and other Officers Superannuation Act so that an officer who has completed a certain number of years of service and is dismissed from his appointment shall be entitled, in the absence of evidence of misconduct, to a pension in accordance with his years of service. . . ."

Most of the Local Government Superannuation Acts protect the officer's right to a pension if he becomes incapacitated by sickness before he has served the statutory number of years. For example, the Asylum Officers Superannuation Act (1909) provides:

"Any established officer . . . who is permanently incapacitated for asylum duties after ten years' service by injury or illness, mental or bodily, medically certified and not attributable to his own misconduct, shall be entitled, on resigning or otherwise ceasing to hold office or employment, to receive during life or incapacity a superannuation allowance. . . ."

An extension clause to protect the officer's service pension might read thus, in accordance with your views:

"Any established officer who after ten years' service ceases to hold office or employment shall, in the absence of evidence of misconduct, be entitled during life to a superannuation allowance in accordance with his years of service."

Your article envisaged prompt action on the part of the Council of the British Medical Association with a view to clearing up the present unsatisfactory position. It may therefore be desirable to point out that an opportunity now presents itself for obtaining almost immediately such a measure of security in the case of at least officers in mental hospitals. I refer to the Mental Treatment Bill which is now before Parliament. The introduction of this bill has been made the means for obtaining administrative changes long overdue in the mental service, such as the reorganization of the Board of Control. Various clauses have been incorporated dealing with their terms of service, tenure of service, pensions, etc., among other things. There is thus every reason for asking that further clauses should be introduced to deal with the terms of employment of the staffs in the asylums, who will be in more intimate contact with the patients for whom the bill was ostensibly brought forward. It is to be hoped that those who will have to negotiate with the Ministry of Health, and to take parliamentary action on behalf of the profession, will endeavour to get such clauses included in the bill.

A bill which envisages such important developments in the activities of mental hospitals would be incomplete if it lacked safeguards such as that recommended by the Royal Commission on Local Government, and your own suggestion about pension protection.—I am, etc.,

Wedmore, Jan. 2nd. H. C. McMANUS.

SANITATION ON THE RIVIERA.

SIR,—The observations of your correspondent Colonel R. H. Elliot (December 28th, 1929, p. 1220) are certainly not applicable to all places on the Riviera. From personal experience I am in agreement with his remarks about Nice, where sanitation is very defective, yet in a place like Alassio on the Italian Riviera, where I am spending my second winter, sanitation is all that can be desired. Sewage is carried out to sea a long way east of the town by a main sewer. The streets are kept clean and well watered and sometimes oiled. No refuse bins are exposed in the streets, but a motor refuse van provided with a crane lifts up all refuse contained in receptacles kept covered below the level of the street, and rapidly conveys the refuse away to special dumping areas. The water supply is pure, and is brought down in a main from the snow mountains north-east of Alassio. The foreshore is sandy along its whole front, and provides a splendid bathing beach.—I am, etc.,

Alassio, Jan. 1st. C. R. KILKELLY, M.B., D.P.H., Colonel (ret.).

SYSTEMATIC INSTRUCTION IN RADIOLOGY.

SIR,—Why does not radiology, a science which has claimed more British martyrs than any of the other ancillary sciences, assume its proper position in this country? Too often it is the resort of the destitute, patients being sent to the radiologist only after the clinician has tried every other diagnostic procedure. If, as is then only too likely, the skiagram fails to give the required information, unfavourable comments are made about one of the most accurate aids to diagnosis we possess. There is a sharp distinction between knowing how to take a radiogram and knowing what a radiogram will show. The practitioner may acquire a valuable knowledge of radiology without learning anything about actual plant. While the origin of x rays is still a matter of dispute, their action is thoroughly well understood, and may be summarized in the statement that x rays penetrate different media to differing extents, thus casting shadows of different densities. The doctor who has grasped this basic principle can build up a useful knowledge of radiology.

It has been suggested that if radiology is popularized everyone would be stimulated to acquire a plant for himself, to the detriment of the science. There is no reason why this should occur, if in courses of instruction to general practitioners it is made clear that technique should always be left in the hands of those who have undergone the prescribed training. The duration of the courses for the D.M.R.E. or M.S.R. should sufficiently deter anyone from dabbling in radiology. While, however, there are excellent courses for the specialist in radiology, there are none for the general practitioner. I suggest that half a dozen lectures are enough to lay the foundations of a useful knowledge of the subject.

The "pathology of the living" is but now receiving the attention it deserves. Apart from operation, radiology offers the only way of visualizing the interior of the body; by its means one can watch the niche of a gastric ulcer slowly becoming shallower, and finally disappearing, as Professor MacLean has shown it does under the intensive alkali treatment. One can watch the furred appearance of active phthisis giving place to the nodular appearance of the healed form, or one can visualize the stages of repair in osteomyelitis or the advance of a bone sarcoma. In all parts of the country x-ray apparatus is being installed at the smaller hospitals, and competent radiologists and radiographers are being appointed; but the work is often hampered because the local practitioners do not know the help that x rays can offer them. Radiologists complain, indeed, that their burdens are heavy enough already without lectures. I suggest that their burdens are heavy because they are being saddled with so much unsuitable work—with cases in which the diagnosis can be made clinically, or in which the x rays could not be expected to offer help. I do not suggest that as a result of giving lectures their burdens would necessarily be lightened; they would probably get more work, but they would have the compensation of getting suitable cases, and their work would thus be more interesting.

It is doubtful whether the student should be inflicted with more lectures, though there can be no doubt that the graduate suffers from the lack of systematic lectures in radiology. In London we have professors in almost every branch of medicine except radiology, though this is probably the best handmaiden the clinician ever had. Surely it is the State's duty to provide practitioners under the National Health Insurance Act with the means of learning what radiology can do and how it can help them. If a fraction of what is now being spent on radium were devoted to the teaching of radiology many lives would be made happier and, what is more, many years of life would be added to thousands of patients, especially those suffering from cancer, because diagnosis would be made earlier, and operation would be performed at a time when it might be expected to do good.—I am, etc.,

London, W., Jan. 1st. A. P. BERTWISTLE, F.R.C.S.Ed.

A SIMPLE CONTROL FOR INSULIN INJECTIONS.

SIR,—In your issue of January 4th (p. 54) "District Medical Officer" inquires about a simple plan for giving insulin. For the last ten years I have been using regularly a method which has proved adequate, reliable, and very simple (described in the *British Medical Journal*, June 6th, 1925, p. 1033).

The evening specimen of warm urine is left overnight in a pint thermos flask to ferment with a little yeast, which destroys any sugar present. The flask must be full and lightly corked. The gravity of the urine is taken before and after fermentation. The difference represents the amount of sugar in grains per ounce. The gravities (before and after fermentation) are plotted as two curves in a child's squared arithmetic book. When the two curves have been coaxed by diet and insulin just into apposition, urinary sugar is absent and the dosage is correct. Any error in diet is at once apparent in the curves, both to patient and doctor. Hence calories are redundant. I give a strict carbohydrate-free diet (unweighed), and allow 3 to 5 ounces of bread—never less, for fear of ketones appearing. These are tested for by liquor ferri perchlor.,

a dark brown colour indicating urgently the need for more bread and more insulin. Insulin is administered twice daily, at first by a nurse, later by the patient. Gluten breads are rarely needed. Insulin cannot be given either safely or effectively unless the urinary sugar is measured daily. If this is done blood sugars are seldom required, except in coma.

It is a mystery to me (and my patients) why this simple and satisfactory system has not come into more general use.—I am, etc.,

Hull, Jan. 7th.

THE PLACE OF THE STATISTICIAN IN MEDICAL RESEARCH.

SIR,—A note on the factors in the production of blackwater fever in the *Journal* of October 18th, 1929 (p. 729), mentions an article of mine which appeared in the *Kenya and East African Medical Journal* of the previous June. Unfortunately, your reviewer appears not to have understood the article, and misinterprets several points.

Conclusive evidence on any subject must be based on experience, or on the particular type of experience termed experiment. For a proper analysis and interpretation of medical experience co-operation between clinicians and statisticians is essential. The belief that an analysis of blackwater fever cases alone, based on their antecedents, can afford any evidence of causality is, to a competent statistician, absurd; but so-called "evidence" of this kind is commonly quoted in medical literature on the subject. If it were shown that of blackwater fever cases 75 per cent. had taken quinine and 90 per cent. had taken tea within twenty-four hours of the attack, this evidence—if it were evidence—would be stronger against tea than against quinine!

It is of the greatest importance that conclusions based on false logic should be discredited, especially in this case, where the treatment of serious malaria is often modified in accordance with the conclusions. I therefore attempted to show, as simply as possible, the correct statistical method of investigating the hypothesis that quinine and blackwater fever were causally related. By taking imaginary figures I showed that the correct method and the "common" method might lead to opposite conclusions. By quoting some very incomplete figures I suggested that quinine might have been falsely suspected. I pleaded that a proper statistical investigation was warranted

I should be glad if you would allow me to make the following corrections. My qualifications are mathematical and scientific—not medical. Groups of cases do not have to be investigated. The method consists in classifying a population into eight groups and counting the number of individuals in each group. I did not mention as a difficulty the minimum quantity of quinine, but the maximum period of time between the dose and the onset. Your reviewer speaks of "number of patients investigated," when my whole point is that to investigate patients is useless. I wrote, "No conclusion can be based on such small numbers, but their interpretation is as follows," which your reviewer changes to "He [Dr. Arnell] believes . . ." —I am, etc.,

O. R. ARNELL.

Kenya, Nov. 25th, 1929.

Obituary.

WE regret to announce the death, at the age of 60, of DR. ROBERT MATTHEW FENN, at his residence in Sheffield, on December 15th, 1929. He received his medical education at Edinburgh, where he graduated M.B., C.M. in 1890. An earnest evangelist from early youth, he determined, after graduation, to continue evangelistic work, and for seventeen years he superintended the work of the Red Bank Medical Mission in Manchester, where he is gratefully remembered to the present day. While there, Robert Fenn devoted himself particularly to diseases of the ear, throat, and chest. He was honorary assistant physician to the Manchester Hospital for Diseases of the Throat and Chest from 1895 to 1901, and physician to the Sunnyside Home for advanced tuberculosis cases. In 1913 Dr. Fenn married and went to Cuzco, Peru, where for a little over two years he conducted medical missionary work. Returning to England in 1915, he received a commission in the R.A.M.C., and was appointed to the Berrington War Hospital, Shropshire, where, soon afterwards, as major, he became second officer in command under Colonel C. Rundle. In 1921 he settled in Sheffield, and was appointed district tuberculosis officer in the West Riding of Yorkshire (Rotherham area); he studied at the University of Sheffield, and obtained the D.P.H. in 1922. Robert Fenn's life and work were characterized by unvarying conscientiousness and thoroughness, coupled with a sincere personal interest in his patients' needs—medical, temporal, and spiritual; many instances are known of his unostentatious help to the necessitous, even when his circumstances could ill afford such gifts. He leaves a widow and young son.

DR. JOHN FORRESTER-WOOD, whose death occurred on December 2nd, 1929, at Bettws-y-Coed, North Wales, was for twenty-five years a well-known practitioner in Southport. Born in 1867, and educated at Atherstone Grammar School and St. Bartholomew's Hospital, he obtained the diplomas M.R.C.S., L.R.C.P. in 1889, and became F.R.C.S.Eng. in 1896. After qualifying he acted as house-surgeon to the Gloucester Infirmary; later he made one or two voyages to the East as a ship surgeon. In 1896 he married, and subsequently settled in Southport. He was a member of the British Medical Association and a vice-president of the Southport Division. A colleague writes:

Dr. Forrester-Wood rapidly gained for himself many friends and an increasing practice; he was an excellent all-round man and a wise adviser, and with these qualifications he soon obtained a prominent position among his colleagues in Southport. He was president of the Southport Medical Society, in which he took considerable interest. During the war he served on the staff of the V.A.D. hospitals and the military annexe of the Southport Infirmary. For many years he acted as surgeon to the Bradstock Lockett Home for Crippled Children, to which he gave devoted service. In 1919, his health not being good, he was advised to seek relaxation in retirement, and he left Southport and went to live at Bettws-y-Coed, North Wales. Dr. Forrester-Wood was a charming colleague and a good friend. He was an excellent sportsman, and delighted to discuss with his intimate friends his success with rod and line. Although he had been absent from Southport for ten years his death will be felt by a large circle of friends, who still remember with affection his many kindnesses to them while he resided there. To the writer of these few lines he was a dear friend and colleague, and his death leaves a sad blank. A widow and three sons survive him, two of whom are in the medical profession.

DR. WILFRED JAMESON died on December 8th, 1929, at his residence at Pontesbury, Shropshire, after an illness of some weeks' duration. Though he had suffered from an affection of the throat for the last twelve months, he continued to practise until a few weeks before his death. Dr. Jameson received his medical education both in Dublin and in Edinburgh; in 1892 he obtained the diplomas L.R.C.P., L.R.C.S.Ed., and L.R.F.P.S.Glas. He started practice in Pontesbury thirty-one years ago, but his residence there was interrupted for a time when he joined Methuen's Horse and went to South Africa. Returning to civil life, he collected a large circle of friends from all classes. In his early days he was an enthusiastic Rugby footballer, and took a prominent part in local sport. During the late war Dr. Jameson held a commission in the R.A.M.C., and served for two years in Mesopotamia, after which he was invalided home. He was an ardent supporter of the British Legion, and was chairman of the local branch from its inauguration until the time of his death. He was a keen member of the British Medical Association. He leaves a widow and one daughter. His funeral took place on December 11th, in the parish church, and was very largely attended. A colleague writes: Dr. Jameson was exceedingly popular and highly respected. By his death the district loses an able physician and a loyal friend.

Dr. HOWARD DAVIES of Pontypridd, who died on December 23rd, 1929, in his sixty-eighth year, received his medical education at Charing Cross Hospital, and obtained the diplomas M.R.C.S. and L.S.A. in 1884. In the same year he succeeded his uncle, Dr. Rhys Hopkins, in a large practice at Pontypridd. From 1884 to 1911 he was medical officer of health for the town, and resumed these duties while his successor was on active service during the war. In 1884 he was appointed medical officer for the Pontypridd board of guardians, and held this post—which involved medical supervision of the Central Home, the Cottage Homes, and the Maesycoed Homes—until he died. He was also surgeon to the police, the Maritime Collieries, and the local St. John Ambulance Division, and treasurer to the Glamorgan Panel Committee; before and during the war he was the local recruiting medical officer. He was a member of the British Medical Association. He was devoted to various forms of sport, particularly cricket, and was president of the local cricket club. He interested himself also in the acquisition of Ynysangharad Fields as a public park, and was responsible for the establishment of the improved local water supply and drainage. He is survived by his widow and one daughter.

We regret to record the death, at the age of 47, of Dr. THOMAS EVANS FRANCIS, O.B.E., late medical officer of health and school medical officer for Barnsley, Yorks. A year ago he was obliged to give up work on account of severe illness, and he resigned his appointments in the spring of 1929. Having recovered sufficiently to undertake a ship surgeoncy, in the autumn he sailed for the East, but in the tropical heat had a recrudescence of bronchitis, and died after some weeks in hospital at Colombo, Ceylon. Thomas Francis received his medical education at Cardiff, and St. Mary's and St. Bartholomew's Hospitals; he graduated M.B., B.S.Lond. in 1905. Being attracted to public health work, he proceeded M.D. in State Medicine two years later, and was appointed medical officer of health and school medical officer for Llanelly in 1910. He served in the Territorial Force (Sanitary Service), and also for several years in the navy—in H.M.S. *Britannia*, H.M. Hospital Ship *Soudan*, and at the Royal Naval Hospitals at Haslar and Plymouth. The O.B.E. (Military Division) was awarded him in 1919. From 1920 till 1929 he held the appointments of medical officer of health and school medical officer for Barnsley, Yorks, where his intelligent zeal for measures likely to benefit the health of the community was highly appreciated. He published several papers in public health journals. He was chairman of the Barnsley Division of the British Medical Association from 1922 to 1927. A colleague writes: Throughout his work Francis never spared himself the trouble of thinking, and, having made up his mind, he was prepared to fight for his ideas. He leaves a widow and three children, one of whom, the eldest son, is taking a medical course in London.

The death took place, on December 27th, 1929, at his residence, Loganbank, Cupar, Fife, of Dr. WILLIAM SNEDDON. He was born in 1859 at Liberton, near Edinburgh, and at first adopted teaching as a profession. He afterwards studied medicine at Edinburgh University, where he graduated M.B., Ch.B., and in 1885 settled in practice at Cupar. For many years he had been one of the best-known practitioners in Fifeshire. He took a great interest in vocal music, and, possessing an excellent baritone voice, was in great demand for his services in the musical world as a soloist and demonstrator.

The following well-known foreign medical men have recently died: Professor LOUIS LEWIN, a Berlin pharmacologist, aged 80; Dr. ERNST GRASER, formerly director of the surgical clinic at Erlangen; Dr. JESSNER, a dermatologist and venereologist of Jena, aged 70; Professor GIOVANNI MIRGAZZINI, an eminent neurologist of Rome, aged 70; and Professor LOUIS PHILIPPSON, director of the dermatological clinic at Palermo.

Medico-Legal.

NEGLIGENCE ALLEGED AGAINST MEDICAL SUPERINTENDENT.

IN the Court of Session, Edinburgh, on December 21st, 1929, judgement was delivered by the Lord Ordinary (Lord Fleming) in an action brought by Duncan Carmichael, a dairyman, against the representatives of the late Dr. Alexander C. Miller, formerly medical officer of health for Fort William, and medical superintendent of the hospital there, for the alleged professional negligence of Dr. Miller in the treatment of one of Carmichael's children.

The child, Duncan, aged 2½ years, was admitted to hospital with scarlet fever on December 31st, 1925. Recovery proceeded normally until the following January 26th, when there appeared what was diagnosed as a secondary or supervening attack of scarlet fever, accompanied by pyrexia, sore throat, and copious rash. Recovery from this attack was complicated by otorrhœa. By March 1st the ear discharge had become slight and intermittent, and the patient was returned to his home. Six days later his brother and sister were admitted for diphtheria, and the sister died. Seven weeks afterwards yet another child was admitted for diphtheria. On the same date as this last admission the original patient, Duncan, was readmitted for recurrent otorrhœa, and it was reported that a swab had shown bacilli morphologically resembling diphtheria bacilli. He was retained until August 3rd, when he left hospital as cured, but a fortnight later he was readmitted for recurrence of the ear discharge, and subsequently his tonsils and adenoids were enucleated. He had still another recurrence, and was not finally discharged until June 8th, 1927.

The grounds of the allegation against Dr. Miller were that when the patient was first discharged from the hospital he exhibited post-diphtheritic symptoms, in addition to the ear discharge, and that the supposed secondary attack of scarlet fever was in fact an undiagnosed attack of diphtheria, with the result that, after leaving hospital, he infected other members of his family, one of whom died. It was further urged that Dr. Miller should have made a bacteriological examination of the ear discharge, and that had he done so it would have been apparent that it was not safe to discharge his patient.

Judgement of Lord Fleming.

Lord Fleming, in giving judgement, said that Dr. Miller, whose professional qualifications were of a high order, and his assistant, Dr. Mackintosh, came to the conclusion that the patient had a secondary attack of scarlet fever, which, though uncommon, occasionally supervened. Neither of them suspected diphtheria, nor did the fever nurse or the hospital matron. None of the clinical appearances of diphtheria were observed. His lordship had no difficulty in holding that there was no negligence in failing to diagnose diphtheria if Duncan really suffered from it. A more difficult point arose as to Duncan's condition at the time of discharge. The pursuer [plaintiff], his wife, and sister-in-law had testified that he had post-diphtheritic symptoms—namely, squint, nasal speech, and unsteady gait; this was contradicted by Dr. Mackintosh, the nurse, and the matron, who said that of these symptoms only unsteadiness in walking was present, owing to long confinement in bed. His lordship believed the doctor, nurse, and matron to be careful and reliable witnesses, who had seen the child constantly just before discharge, and he preferred their evidence to that given on the other side. Dr. M'Iver, a witness for the pursuer, first saw Duncan on March 7th, six days after discharge, and said that he noticed post-diphtheritic symptoms. If, in fact, Duncan was suffering from post-diphtheritic palatal paralysis, as Dr. M'Iver had said, his condition was one of some gravity, yet Dr. M'Iver took no steps to advise as to treatment, and though he apparently believed that Duncan had infected his sister and brother he said nothing to the parents about isolation, nor did he communicate his suspicions to Dr. Miller. Dr. M'Iver failed to take the steps which one would have expected of him, and his lordship was inclined to doubt whether the post-diphtheritic indications were as clear to him at the time as he now thought them to have been. The recurrence of the discharge from the ear alarmed the mother, who sent for Dr. M'Iver; he took a swab from the throat, which was reported negative, and, later, one from the ear, which was reported positive, upon which Duncan was readmitted to hospital. It was difficult to believe that, until he received that positive report, Dr. M'Iver was satisfied that Duncan was suffering from the sequelæ of diphtheria.

As to whether Dr. Miller could reasonably be charged with negligence for allowing Duncan to leave the hospital with his ear still discharging, it was proved in evidence that ear discharges after scarlet fever might continue for years, so that if it were laid down that patients should never be discharged until the otorrhœa had ceased it would be necessary to retain them for

very long periods. It was not in contravention of usual or reasonable medical practice to discharge patients suffering from intermittent scarlet fever otorrhoea. One of the witnesses for the pursuer, Dr. Gillies, medical officer of health for Argyll, agreed that it was quite a common practice to discharge patients in that condition, and Dr. Archibald testified that he had discharged from Belvidere fever hospital, Glasgow, about 300 scarlet fever patients suffering from otorrhoea, and had not been able to trace any return. Dr. Miller could not be held to have fallen short of the standard of care and skill practised in his profession by discharging Duncan before the otorrhoea had finally ceased.

It could not be disputed that the sequence of events was in favour of the pursuer's case, and the bacteriological examinations of swabs taken from Duncan's ear proved that diphtheria bacilli were present, but the fact that negative as well as positive results were obtained suggested that they were not numerous. The proof that the other children were infected from Duncan, however, broke down, because it had not been established that virulent bacilli were ever present in the discharge from the ear. Diphtheria bacilli might be virulent or avirulent, and infection could only be transmitted by the former type, and the types were definitely immutable. Only a biological examination could disclose to which of these types a diphtheria bacillus belonged, but in practice, if the clinical symptoms indicated that the patient was suffering from diphtheria, and the microscopic examination showed the presence of diphtheria bacilli, it was naturally assumed that the bacilli were virulent. In the present case there was no clinical history to show conclusively that Duncan ever suffered from diphtheria, and biological examinations which had been made on two occasions showed that the bacilli were of non-virulent type. If, therefore, the question had to be decided as to whether Duncan infected his brothers and sister, his lordship said that he would have to hold that the pursuer had failed to prove tha tthe diphtheria of which his daughter died had been contracted by infection from Duncan. The pursuer had experienced a remarkable series of misfortunes with regard to his children, and it was perhaps natural that he should think there must have been some carelessness. The evidence, however, showed that not only was Dr. Miller not guilty of negligence, but the pursuer's children received all proper care and attention while in his charge. The defenders [defendants] were accordingly entitled to be assoilzied [absolved].

The defence in this case was undertaken by the Medical and Dental Defence Union of Scotland.

CHRISTIAN SCIENCE HOME CENSURED BY CORONER'S JURY.

AT an inquest held at Ealing, on December 14th, 1929, on the body of a Mrs. Lundy, who died from injuries consequent upon jumping from a window in a Christian Science home at Greenford, the proprietress of the home, Mrs. Gertrude Robinson, was censured by the jury for not taking precautions to protect the deceased from a suicidal tendency of which she was made aware, for not immediately calling in a doctor after the woman's fall, and for omitting to inform the relatives at once of the occurrence. A verdict of "Suicide during temporary insanity" was returned. The coroner made it plain that he did not endorse the jury's censure.

It was shown in evidence that the deceased lady, who was not herself a Christian scientist, was taken to the home temporarily by a brother. A previous threat to jump out of a window was mentioned to the proprietress, who said that the windows were fastened. On the following morning, having induced the nurse in attendance to leave her for a moment, the deceased went to a landing window and jumped out. The daughter of the lady was not informed of what had happened until late at night, two hours after death. According to the nurse, the woman behaved quite normally after the fall, and was able to move her limbs and to speak with ease. The proprietress said that had she realized that there was severe injury she would have called in a doctor. In reply to the coroner, who said, "I thought it was against your belief," Mrs. Robinson replied, "Yes, it is, but there are certain emergencies for which there are rules we cannot ignore." She did not inform the relatives because she did not think the woman was badly hurt, and she did not want to upset her. Dr. M. H. Renall testified that death was due to a fracture of the spine which would have been very difficult even for a medical man to detect without *x* rays. Asked whether, had he been called in, he could have saved the woman's life, he replied, "I think not."

The coroner said that it was easy enough to be wise after the event, but it seemed to him that it might have happened in any home. He was sure the jury would be wise and broad-minded enough not to find fault because it happened to be a Christian Science home. The jury, however, returned the rider stated, the coroner remarking, "It is the jury's verdict, not mine."

Universities and Colleges.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

PROFESSOR A. V. HILL, F.R.S., will give a course of four public lectures on oxygen and the recovery process in muscle and nerve on January 20th, 27th, February 3rd and 10th, at 5 p.m.

A course of four public lectures on chemistry of muscle in relation to problems of cellular physiology will be given by Professor Otto Meyerhof, Director of the Institute of Physiology, Kaiser Wilhelm-Institut, Berlin, on March 6th, 7th, 10th, and 12th.

Two public lectures on the growth and developmental mechanics of bone will be given on March 11th and 13th by Professor J. C. Brash, Dean of the Faculty of Medicine, University of Birmingham.

The second term of a course of post-graduate lectures in biochemistry, to be given on Thursdays and Fridays at 4 p.m., will commence on January 16th.

UNIVERSITY OF BRISTOL.

DR. R. J. BROCKLEHURST, who has been appointed to the chair of physiology in the University of Bristol, received his medical education at Oxford and St. Bartholomew's Hospital; he graduated B.M., B.Ch. in 1924 and D.M. four years later. He held the appointment of demonstrator in physiology at St. Bartholomew's Medical College, 1925–26; was awarded a Radcliffe Travelling Fellowship, with the aid of which he travelled in America and Germany from 1926 to 1928; and returned to take up the post of lecturer at University College in August, 1928. His appointment at Bristol will come into force on August 1st.

Medical News.

A MEETING arranged by the Metropolitan Counties Branch of the British Medical Association will be held at the B.M.A. House, Tavistock Square, W.C.1, on Tuesday, February 11th, at 5.30 p.m. Dr. Francis R. Fraser, professor of medicine in the University of London and physician to St. Bartholomew's Hospital, will give an address entitled "Before the Finals and After." Fourth and fifth year students and recently qualified medical practitioners are cordially invited. Tea and coffee will be served at 5 p.m.

SIR GEORGE NEWMAN will give four Gresham Lectures on physic at Gresham College, Basinghall Street, E.C., on February 4th, 5th, 6th, and 7th, at 6 p.m. The lectures are open to the public without charge or tickets.

THE annual meeting of the Royal Microscopical Society will be held at 20, Hanover Square, W.1, on Wednesday, January 15th, at 7.30 for 8 p.m. Mr. Joseph E. Barnard, F.R.S., will deliver his presidential address on resolution and visibility in medical microscopy.

VISCOUNT GREY OF FALLODON will take the chair at the meeting of the British Institute of Philosophical Studies to be held at the Royal Society of Arts, 18, John Street, Adelphi, W.C.2, on Tuesday, January 14th, at 8.15 p.m. Principal L. P. Jacks will deliver a lecture on the philosophy of adult education.

AT a meeting of the General Council of King Edward's Hospital Fund for London, held on January 6th, with Lord Somerleyton in the chair, it was reported that H.R.H. The Prince of Wales, President of the Fund, had appointed the Lord High Chancellor (Lord Sankey), the Speaker of the House of Commons (Captain the Right Hon. Edward Fitzroy, M.P.), and the Governor of the Bank of England (the Right Hon. Montagu Norman), to exercise his powers as President during his absence from England.

THE Fellowship of Medicine and Post-Graduate Medical Association has arranged an all-day course in diseases of children at the Queen's Hospital for Children from January 13th to 25th. Fee £3 3s. for the two weeks; simple lunch and tea kindly provided by the hospital authorities. From January 27th to February 8th an intensive course in medicine, surgery, and the specialties will be given at the North-East London Post-Graduate College (Prince of Wales's Hospital, Tottenham, N.15). The fee for the course is £5 5s., or £3 3s. for either week. On January 21st the Fellowship of Medicine will start a new series of lectures, at the Medical Society of London lecture room, on successive Tuesdays at 4 o'clock. Graduates are requested to note the change of day and time of these lectures, which are free to the medical profession. The new series of clinical demonstrations in medicine and surgery at the various London hospitals will open on January 23rd. In addition to the special courses arranged for 1930 the Fellowship provides a general course which consists of the clinical practice of its associated hospitals. A programme is provided for ticket holders, which sets out the clinics under subject headings, leaving the graduate free to make out his own time-table. This course

is continuous throughout the year, and may be begun on any day of the week. Inquiries should be addressed to the secretary, Fellowship of Medicine, 1, Wimpole Street, W.1.

UNDER the auspices of the National Association for the Prevention of Infant Mortality a course of post-graduate lectures on maternity and child welfare intended for health visitors, nurses, midwives, and superintendents of infant welfare centres, will be given in the lecture hall at Carnegie House, 117, Piccadilly, W.1, on Monday evenings from 6.30 to 7.30, from January 20th to March 24th. A course of lectures on infant care, specially intended for crèche nurses and probationers, will be given at the same address on Thursday evenings, from January 23rd to March 27th from 7.30 to 8.30. Further details may be obtained from the honorary secretary of the National Association, at Carnegie House.

UNDER the auspices of the British Institute of Philosophical Studies a course of six lectures on some aspects of the moral life will be given by Professor W. G. de Burgh of the University of Reading on Thursdays, January 16th to February 20th inclusive, at the Royal Anthropological Institute, 52, Upper Bedford Place, W.C.1, at 5.45 p.m. The fee for the course for others than members of the Institute is 12s. 6d. A course of four lectures on science and art will be given by Professor S. Alexander, of the University of Manchester, at the Royal Anthropological Institute on Fridays, January 31st to February 21st inclusive, at 5.45 p.m., the fee being 10s. Applications for the syllabus and form of registration should be addressed to the director of studies, 83, Kingsway, W.C.2.

A COURSE of lectures on the construction and operation of x-ray and electro-medical apparatus has lately been started at the Austrian State Engineering and Electrical Institute in Vienna.

THE Royal Institute of Public Health will hold a congress in Portsmouth from June 4th to 9th. The scientific work of the meeting is being arranged in five sections, dealing respectively with: State medicine and municipal hygiene; naval, military, and air (including tropical) diseases; industrial hygiene; women and children and the public health; and tuberculosis. Delegates are being invited from public bodies in Great Britain and Ireland, France, Italy, Germany, and the United States. Further information may be obtained from the honorary secretaries of the congress, Royal Institute of Public Health, 37, Russell Square, W.C.1.

THE second Pan-American congress will be held at Panama under the presidency of Dr. Francesco Fernandez, Minister of Health for Cuba, from January 30th to February 5th, and will be attended by representatives of all the American republics and the Dominion of Canada. An exhibition will be held at the same time, showing recent progress in American hospitals and laboratories.

THE forty-fifth congress of the Berlin Balneological Society will be held at Bad Elster from April 9th to the 13th, under the presidency of Professor Dietrich. The congress will be preceded by an inspection of the buildings of Leipzig University, and followed by a visit to the sanatoriums in the neighbourhood. The chief subjects for discussion at the congress are the importance of iron in spas, mud baths, and the diet of patients at health resorts. Further information can be obtained from the general secretary, Dr. Max Hirsch, Steglitzstrasse 66, Berlin, W.35.

THE first international congress for psychical hygiene will be held at Washington from May 6th to 10th.

THE Henry Saxon Snell prize, which is awarded by the council of the Royal Sanitary Institute at intervals of three years, is offered in 1930 for an essay on improvements in the sanitary provisions of schools. The prize will consist of fifty guineas and the medal of the Institute. Typewritten essays of not more than 5,000 words, and illustrated by drawings or sketches, must be received on, or before, August 30th, by the secretary of the Institute, 90, Buckingham Palace Road, S.W.1, from whom further details may be obtained.

AN address on the growth of the mind, delivered as the Ninth Henderson Trust Lecture by Sir Robert Armstrong-Jones at Edinburgh University on November 29th, 1929, has now been published as an attractively illustrated pamphlet of thirty pages, and may be obtained from Messrs. Oliver and Boyd (Edinburgh and London: price 6d.). The Trust was founded by William Ramsay Henderson, who, in 1829, made a trust-disposition and settlement, requesting his trustees to assist in advancing the knowledge of brain physiology—at that time referred to as phrenology, cranioscopy, or organology. The previous lectures have been delivered by Professor G. Elliot Smith, Sir James Crichton-Browne, Sir Arthur Keith, Professor W. W. Graves, Professor Karl Pearson, Dr. Robert D. Clarkson, Professor Cyril Burt, and Dr. W. Norwood East.

THE King has confirmed the appointment of Dr. Aubrey Montague, chief medical officer, Fiji, as a nominated member of the Legislative Council of the colony of Fiji.

THE issue of the *Wiener medizinische Wochenschrift* for January 1st contains a reproduction in small type of its first number, published on April 5th, 1851.

The *Police Journal*, an excellent and well-produced quarterly review for the police forces of the Empire, usually includes one or more articles of medical interest. In the current issue, dated January, 1930, we note "Superstition and Crime in India," by H. R. Roe; "The Drug Traffic in the Punjab," by F. L. Newman; "Age and Crime," by James Devon; and, of more general interest, an article on the policeman in fiction.

IT is announced that Sir Woolmer White, formerly chairman of the hospital, is the anonymous benefactor who offered £10,000 for the enlargement and modernization of the Royal Portsmouth Hospital on condition that a like sum was raised by public subscription. This object has now been attained and £30,000 is available for the hospital.

THE London County Council is proposing to erect, in connexion with Banstead Mental Hospital, a detached building to serve as an admission hospital, designed on modern lines for the accommodation of 100 patients, 50 of each sex. This provision, besides giving the facilities for classification and treatment which are now recognized to be essential, will add to the total accommodation of the hospital, and so will help to meet the increasing demand which is being made upon the Council for beds for mentally afflicted patients. Banstead Mental Hospital has not hitherto possessed an admission hospital.

THE following appointments of members of the medical profession to the Venerable Order of the Hospital of St. John of Jerusalem are announced. *Commanders:* Dr. Charles Bage, Dr. John J. Holland, Lieut.-Col. Hugh R. G. Poate, Dr. Leslie W. Dryland, Dr. Nigel C. Fletcher, Dr. Gilbert P. Mosscrop. *Officers:* Dr. Harry L. Brownlow, Dr. Frank Hichens, Major Robert D. Cran, R.A.M.C.T., Lieut.-Col. Alexander R. Falconer, Sir Louis E. Barnett, Dr. John B. Gunson, Dr. Gustave H. Hogg, Dr. James H. G. Robertson, Dr. Alexander N. McKelvey, Lieut.-Col. Harry Spackman, late R.A.M.C., Colonel Astley V. Clarke, M.D., Dr. Daisey E. Platts-Mills, Mrs. Elizabeth G. Stewart, M.B. *Serving Brothers:* Dr. Arthur P. Gibbons, Dr. Arthur B. Cardew, Dr. Cecil Hibbert, Dr. John Murray, Dr. John W. Wyncoll, Dr. James L. Callaghan.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medicera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62553 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

SENSATION OF COLD IN THORAX.

DR. L. W. K. SCARGILL (Whitby) asks for suggestions that may help him in the treatment of a patient who complains of a cold band across and around the chest. The distribution corresponds roughly to the third and fourth thoracic segments. The patient describes the symptom by saying that he feels as if he was always sitting in ice-cold water, with the surface just above the nipples.

FACIAL NEURALGIA.

"R. B. M." asks for advice in treating a case of persistent neuralgia affecting the right side of the face in a man aged 70. The pain is shooting in character, and the corner of the mouth and upper lip are so sensitive that the patient cannot eat solid food. All the teeth are absent; there is no evidence of neoplasm, and an *x*-ray examination of the bony structures is negative.

TRAIN SICKNESS.

IN reply to the inquiry of "J. T. M." in the *Journal* of December 21st, 1929 (p. 1184), Dr. LESLIE B. HARTLEY (London, W.) writes: I would advise "J. T. M." to have the child's eyes examined, if he has not already done so, since errors of refraction may cause nausea and vomiting when travelling. A girl, aged 8, came to me for re-examination to-day; I had prescribed spectacles for her fourteen months ago. At the time she was complaining of "eye-strain," and I found that she had one dioptre of astigmatism in each eye. I prescribed spectacles for this, and told her mother that the child should wear them for near work, at cinemas, and for motoring—in fact, when she was using her eyes. The mother had not mentioned that the child suffered from nausea, accompanied by vomiting, in trains and in the car, as she had not connected this with her eyes. But the mother told me to-day that, although in the past the child had suffered from nausea and often from vomiting in the car, this had been completely cured since she had worn her glasses. Furthermore, in corroboration of the fact that the spectacles had cured her, the child was violently sick on the only occasion when she went in the car without them; also she had the same symptoms on the only occasion when she watched the lawn tennis championships at Wimbledon without her glasses.

DR. F. G. GARDNER (Oxford) writes: I have found that vomiting caused by long train or motor journeys may be warded off by giving for a few days beforehand a simple stomachic mixture, such as ordinary gentian and soda mixture, or rhubarb and soda mixture, to which small doses of potassium bromide have been added. This treatment might be of use when ordinary travel by bus or train brings on an attack. I think the eyes should be examined, if this has not already been done, since astigmatism may be present, and this may be the cause of the trouble.

DR. J. W. HAUGHTON (Falmouth) writes: I have tried several things for train sickness. The following is the most useful combination for an adult:

R	Chloralamide	15 grains
	Pot. broin.	15 grains
	Tr aurant.	1 dr.
	Aq. chloroformi	1 oz.

If this is given an hour before starting a journey, and repeated in one hour, a third dose can be taken in an hour's time. I have generally found two doses sufficient for the long journey to London from Falmouth. "J. T. M." could reduce the dose of chloralamide to suit the child's age.

TREATMENT OF PRURITUS VULVAE.

DR. AGNES SAVILL (London, W.) writes: "R. S.," in your issue of January 4th (*p.* 54), describes a severe case of the above. X-ray, high frequency, and ultra-violet light should be useful, but if any scratching or rubbing continues the condition cannot be cured. Luminal at night aids sleep; the hands must be bound till the irritation is yielding to treatment. Sometimes it is necessary to paint the area with a strong acid and keep the patient in bed till the raw surface heals. Full details are given in my article in the *Lancet* last spring on the treatment of eczema of the vulva and anus.

DR. PERCY HALL (London, W.1), in reply to "R. S.," writes: Probably local treatment with the Kromayer lamp would give relief. This might further be helped by diathermic fulguration of the "spot."

"F. H. H." suggests that as the application of hot water brings temporary relief, diathermy with a vaginal electrode applied daily will produce more lasting relief. This treatment, combined with the high-frequency vacuum tube excited from a static machine, has invariably produced excellent results in the writer's hands. Improvement is noticed from the first application, and continues in most cases to a successful cure.

DR. J. R. WILLIAMS (Penmaenmawr) writes: I would suggest painting the parts with ol. menth. pip. Over thirty years ago I tried this treatment in a very obstinate case, and it gave immediate relief.

DR. PAUL CAVE (London, W.1) writes: It is not unusual for cases which do not react to any of the usual remedies to respond well to treatment with small doses of *x* rays. I would suggest the local application of three 1/2 pastille doses through 1/2 mm. aluminium filter at intervals of ten days. This treatment should not be repeated, but, if relief is not obtained, a few local applications of ultra-violet rays with a tungsten or mercury vapour lamp might be tried.

"M. G." writes: I had a similar case in which the irritation originated in the anus, but spread to all the surrounding parts; there was a special focus of irritation in the vulva. The patient had a dry, thin skin, dry mucous membranes, and a tight, small sphincter ani. I have no doubt that these conditions, inducing as they did undue spasm of the sphincter, produced the fissures for which she was operated on on two occasions. At the second operation the knife was passed round the anal opening subcutaneously, severing the nerves. The irritation in the anus ceased, but the general irritation was no better. No local treatment was of any use until I thought of using menthol as an antispasmodic. She was given a lanoline ointment containing ammoniated mercury, cyllin, 5 grains of menthol, and a teaspoonful of camphor water to the ounce. This was applied to the anus only; it completely relaxed the spasm of the sphincter, and everything else got well forthwith. The patient has used this ointment for seven years and has remained perfectly well. She never allows the bowels to go for a day without acting, using a warm water injection when necessary. She wears, day and night, a linen handkerchief on a light elastic band, in order to keep the ointment from staining her clothing.

INCOME TAX.

Change in Nature of Appointment.

"NEMO'S" income during the year ended April 5th, 1929, was derived from a hospital house appointment, locumtenent work, and, as from January 21st, 1929, from a salary of £300 per annum, as indoor assistant to a general practitioner. The total amount of his earnings for that year was £141 16s. He has been assessed for the year ending April 5th, 1930, at £300. Is that correct?

*** *Yes.* The rule that income is calculated according to the amount of the previous year applies to each various source of income, but not to income as a whole. For instance, if "Nemo's" salary as general practitioner's assistant should be increased to £350 from April, 1930, he will still be assessable at £300 for 1930-31, but a change in the appointment starts a new basis, and he is chargeable for the first year on the amount of the income of that year.

Change in Partnership: Surtax.

SUPERTAX writes: A, B, and C were in partnership until June, 1928, when B died, and A and C carried on, claiming to be treated as a new business for income tax purposes. A's share of the profit in 1927-28 was £1,600 and in 1928-29 £1,900. On what basis should A render his surtax return for 1928-29 for the tax payable in 1930?

*** The surtax liability must follow the income tax assessment. If we understand the facts correctly, A and C are to be regarded as having started a new business at June, 1928, and will be chargeable to income tax for 1928-29 on their shares of the actual profits—£1,900 in A's case. That being so, the same figure must be adopted for surtax.

LETTERS, NOTES, ETC.

THE RUSTED HYPODERMIC NEEDLE EMERGENCY.

DR. J. N. MORRIS (Plymouth) writes: The following "tip" may prove valuable should one's only available hypodermic needle be found inseparably rusted to the stilet. The rusting occurs near the point, and if the needle is gently snapped across about halfway down, the stilet can be extracted, and the necessary operation performed on the unlucky patient with the stump. This is prevented from ever happening again by seeing that all needles are in proper order.

HERPES AND VARICELLA.

DR. C. EDWARDS (Andover) writes: I do not know if it is of sufficient interest to record another of these combinations which has occurred in my practice: Mrs. C. (mother), herpes of cervical plexus, first seen on December 12th, 1929; Betty C. (infant, aged 1 year), varicella; rash appeared on December 27th, 1929.

OESOPHAGEAL OBSTRUCTION IN CHILDREN.

THERE was an obvious slip in the annotation with this heading in last week's *Journal* at page 28. The sentence beginning at line 11 of the second column should run: "After describing these twelve cases, and emphasizing the practical point that in making an *x*-ray examination a solid rather than a liquid opaque meal should be employed, the authors discuss briefly the subject of cardiospasm or achalasia in childhood."

WINTER MOTORING.

IN connexion with our Motor Correspondent's recent article on "Winter Motoring" (December 7th, 1929, p. 1061), Lodge Plugs, Ltd., Rugby, write to point out that difficult engine starting in the cold weather is frequently caused by the firing points of the sparking plugs having "grown apart," resulting in too wide a spark gap. It is quite an easy matter to close the points up again, but to ensure that they are re-set to the correct distance apart a gauge is necessary. The firm has produced a handy little key-ring gap gauge for this purpose, one of which it will be glad to forward to any of our readers who send a stamped addressed envelope.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 46, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 15.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

32. Pseudo-encephalitic Hypertonicity in Typhoid Fever.

E. MAY and M. KAPLAN (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 4th, 1929, p. 1228) state that a pseudo-encephalitic hypertonic state may occur in typhoid fever in two forms. In the more frequent type there are permanent contractions, either localized—as, for example, trismus—or generalized and tetanic. The second type resembles a Parkinsonian rigidity, but is seldom very definite; it occasionally simulates the meningeal syndrome, and may occur in the lower limbs, but is more frequently observable in the upper limbs, appearing as flexion of the forearm upon the arm, and offering resistance similar to that of true Parkinsonism. In mild cases the "cogwheel phenomenon" may occur. Although this condition causes no discomfort to the patients, yet of four cases in which it was observed by the authors three patients died, and the fourth patient's condition became extremely grave. The authors give details of these four cases. In the first, at the beginning of the third week of the illness rigidity was noticed in passive movements of the forearm; hypertonia increased, accompanied by katatonic rigidity; deep stupor and continuous rigors supervened, and death occurred eight or ten days after hypertonia of the arms had been first observed. In another case hypertonia appeared at the end of the second week; rigors followed with severe pharyngeal spasms, and death occurred in twelve days. The third patient's symptoms assumed a fatal ataxo-adynamic type. The fourth patient, who recovered, proceeded normally for three weeks, when hypertonia of all limbs developed, particularly in the elbows. There were slight tremors and slight involuntary manual movements. The patient remained fully conscious, but the rigidity increased and the features became immobile. Four days later complete aphonia supervened, due to paralysis of the left vocal cord (recurrent laryngeal type). In the fifth week double ankle clonus developed, with incontinence of urine and faeces, and large bedsores appeared. On the forty-second day the rigidity diminished, the voice returned, and the deafness disappeared. The patient was discharged at the end of three months. The authors direct attention to the late development of rigidity in these cases as compared with the very early appearance of meningeal symptoms. In all these cases rigidity was a danger-signal. In two cases lumbar puncture was performed, but the cerebro-spinal fluid was quite normal. The last patient alone exhibited symptoms of involvement of the pyramidal tracts (clonus). No necropsies were permitted, but the authors suggest that the encephalitic symptoms were due to toxic rather than to inflammatory conditions: the hypertonia would then result from enteric intoxication of the nerve centres, analogous to that occurring in tetanus and diphtheria. The evolution of the symptoms indicated that the lesions were mesencephalic, and in the fatal cases it is probable that these extended to the medulla.

33. Massive Collapse of the Lung.

P. BENEDETTI (*Paris Méd., November 9th, 1929, p. 425*) believes that massive collapse of the lung is much more frequent than was thought to be the case a few years ago. Etiologically it can be classified as *post traumatic*; the sequel of some respiratory illness such as *bronchitis*, pulmonary abscess, or tuberculosis; and a *complication* of various conditions, including diphtheria paralysis of the diaphragm, acute poliomyelitis, HCl *poisoning*, *acute meningitis*, malaria, and costal fracture due to neoplasm. There is often a sudden onset with dyspnoea, cyanosis, *pain*, and a sense of thoracic constriction, tachycardia, cough often with expectoration, fever, and leucocytosis, but these symptoms may be absent and the condition be only detected by physical and *x*-ray examination. Unless the condition is bilateral it is rarely fatal, and post-mortem examination is seldom possible owing to the *improvement or cure which* almost invariably ensues. The mechanical and nervous phenomena associated with the signs and symptoms of massive collapse are discussed, and six points are put forward in support of the view that there is a double antagonistic nerve supply to the lung. On the one hand the para-sympathetic influences the expansion of the lung by lengthening the interlobular and pleural muscle fibres, producing a dilatation or diastolic state of the lung; the sympathetic, on the other hand, determines the retraction by causing contraction of the muscles, producing a systolic state of the lung. The innervation of the pleuro-interlobular mechanism is thus, the inverse of that of the muscular system of the bronchi. Physiological experiments on animals are also mentioned which support this view, and, in conclusion, the hypothesis of pulmonary tonicity as applied to cases of massive collapse is put forward to explain the pathology of this morbid condition.

34. Epilepsy and Alcoholism.

L. JARLOW (*Thèse de Paris*, 1929, No. 218), who records six illustrative cases in men aged from 26 to 68, shows that *epileptic* syndromes may occur in the course of the different forms of acute or chronic alcoholism. The symptoms may not appear till late in life when the patient is a latent epileptic, the disease being revealed by an alcoholic excess. Clinically, the epileptiform convulsions of the alcoholic subject are characterized by their localization in one particular group of muscles, their violence, and their association with psychical disturbance. The medico-legal position is stated by the author to be that the alcoholic epileptic patient is responsible for having voluntarily made himself drunk, but is not responsible for acts committed during an attack.

35. Babinski's Sign in the Newborn.

C. JUARROS and A. G. MUÑOZ (*La Med. Ibera*, November 30th, 1929, p. 573) investigated the plantar reflex in 200 newborn children with the following results. In the first hour after birth 96 showed dorsal flexion in both feet; 54 dorsal flexion in one foot and plantar flexion in the other; 6 plantar flexion in both feet; and 8 plantar flexion in one foot and abolition of the reflex in the other. Further examination eight days later showed that the reflexes remained the same in 112 and had undergone changes in 88. The fact that the mother was a primipara or multipara appeared to have *little effect on the* plantar reflex, except in one respect—namely, the greater frequency of a bilateral Babinski sign in the children of primiparae. Abnormal labour also increased the frequency of Babinski's sign. Sex had no influence in determining the nature of the plantar reflex.

Surgery.

36. Oesophageal Varix.

A. VIOLATO (*Il Policlinico, Sez. Chir.*, October 15th, 1929, p. 540) reports a case of rapidly fatal haematemesis in a youth due to rupture of a varix of the oesophagus which communicated with the thoracic aorta. The *patient died* in forty-eight hours, but the only symptoms complained of were malaise and fullness of stomach. Cirrhosis of the liver and symptoms of stasis in the portal system being absent, the haematemesis was attributed to gastric ulcer, the true condition being only revealed by a post-mortem examination. According to Violato oesophageal varices are commonly believed to be due to cirrhosis of the liver; but other causes are recorded, such as stasis of the vena cava produced by a thyroid or pancreatic tumour. Other forms of oesophageal varix have been classified by Dionisi as: (1) senile, due to sepsis and not to stasis; (2) congenital; and (3) occurring in adults without stasis or any obvious cause. Congenital syphilis, puerperal infection, and appendicitis have been named, however, as possible causes. Violato remarks that the differential diagnosis of oesophageal varix is difficult. Chronic gastric ulcers can be excluded by the history of the case, but the acute ulcer remains, particularly that variety in which prodromal symptoms are absent. Portal stasis due to cirrhosis may be absent or, if present, may give rise to no symptoms. If the haematemesis is not quickly fatal, examination with the oesophagoscope is the only means of making a diagnosis before an operation for gastric ulcer is undertaken. The case recorded by Violato has, he thinks, no parallel in the literature. The necropsy revealed a communication of the varix with the aorta, and death should perhaps be attributed more correctly to haemorrhage from the aorta. No cause for such an occurrence could be traced in Violato's patient as in the case recorded by Loeffler, where a tuberculous vertebral abscess led to rupture of the aorta into the oesophagus. For such a rupture to occur the presence of foreign bodies is not necessary, since solid particles of food or a high blood pressure may be responsible for the breaking of an oesophageal varix.

37. Leucoplakia of the Renal Pelvis.

A. A. KUTZMANN (*Arch. of Surg.*, November, 1929, p. 871) defines leucoplakia as a thickening or keratinization of epithelium taking on a definite epidermoid character, and occurring in any part of the body. The leucoplakial membranes resemble skin with characteristic layers of the stratum germinatum, mucosum, granulosum, lucidum, and corneum. The granular layer shows the typical keratohyaline granules seen in the skin, and the cells of the rete have the typical intercellular bridges. Lymphocytic infiltration of the underlying connective tissue is present. With leukoplakia in the urinary tract an ectodermal type of structure occurs in organs of mesodermal and entodermal origin, and is associated with a chronic urinary infection or lithiasis. It is not discovered until operation or at necropsy, since there are no characteristic symptoms, and the patient is usually treated for the associated condition. Leucoplakia may occur in any part of the urinary tract from the renal pelvis to the urethra, and at any time during life, though the fourth decade is the most common. The frequent presence of cystitis, pyonephrosis, tuberculosis, and lithiasis emphasizes the coexistence of infection and stone with leucoplakia, and suggests the possibility of there being an irritative factor in its causation. The two theories with regard to the etiology of leucoplakia are, that the process is one of metaplasia or adaptation and protection by cornification as the reaction to a chronic inflammatory environment; alternatively, that it is of congenital origin due to misplaced embryonal cell rests from the primitive ectoderm. The symptoms are usually dysuria, burning on urination, and frequency, with lumbar pains and backache ranging from the dull type to acute renal colic. The urine shows signs of infection, and pyuria with hematuria in 35.8 per cent. of cases. Careful cystoscopic examination of the bladder may reveal irregular plaques of membranous formation, situated upon a normal or an infected vesical mucous membrane. Treatment may be surgical if only one kidney is infected, but when nephrectomy is contraindicated pelvic lavage with a weak solution of silver nitrate, or curetting of the desquamating membrane, may be tried. Fulguration and the application of radium have resulted in only limited success in vesical cases.

38. Primary Influenzal Appendicitis.

J. ROMANT (*Monde Medical*, October 15th, 1929, p. 954), who records three illustrative cases in patients aged 52, 14½, and 33 respectively, all of whom recovered after operation, maintains that influenza plays a much more important part in the etiology of winter appendicitis than is supposed. The symptoms resemble those of gastro-intestinal influenza, consisting in colic, tenesmus, meteorism, bilious vomiting, and intestinal cramp which may be so violent as to resemble cholera. While spontaneous pain is diffuse and situated in the region of the umbilicus, tenderness is more pronounced in the right iliac fossa. In women the coexistence of an infective oöphoritis can be confirmed or excluded by recto-vaginal examination. Romant considers that the administration of a purgative is a dangerous test, but a rectal injection under low pressure which increases the caeco-appendicular pain is a safe guide. Treatment consists in early operation.

Therapeutics.

39. Acid-Alkali Treatment of Urinary Infections.

VARIOUS investigators have found that *B. coli* grows best in a medium of *p*H 5.0 to 8.0, with 7.0 as the optimum. Most urinary infections are due mainly to this organism, rarely, however, in pure culture, and the administration of drugs to alter the reaction of the urine has long been a recognized form of treatment; recently rapid alternations of acid and alkali in controlling urinary infection have been much used. S. PERLMANN and H. v. SAUER (*Münch. med. Woch.*, October 25th, 1929, p. 1793) have tried a special modification of this method, and report the results in 75 cases of pyelitis and cystitis in the acute, subacute, and chronic stages. No local treatment was given, but the administration of drugs was supported by alterations in the diet. For this purpose the commoner articles of diet were classified under four headings: strongly or weakly alkaline (including milk, tea, most fruits, and vegetables), and strongly and weakly acid (including meat, fish, cheese, butter, and eggs). For making the urine alkaline one tablespoonful of sodium bicarbonate was given three times daily with foods from the alkali groups; for acidifying the urine, camphoric acid (7.5 to 15 grains thrice daily), hydrochloric acid, phosphoric acid lemonade, and urotropine were given, and the diet constructed from the "acid" groups. The change from one to the other form of treatment was generally effected at four-day intervals. It was also found useful to allow plenty of fluids on the alkalizing days, and to restrict the quantity of fluids on the acidifying days. As alkalization generally produces an amelioration of symptoms, and acidification tends to exacerbate them, it is regarded as advisable to start with alkalization. The 75 cases recorded included 36 of pyelitis, 22 of cystitis, 10 of haemorrhagic cystitis, and 7 of pyuria in children; 53 patients were cured, 15 improved, and 7 were unaffected by the treatment. When the treatment was continued for some weeks it was possible to cure cases of chronic infection of long standing. In the refractory cases such conditions as stricture of the ureter or prostatitis were subsequently found. Perlmann and v. Sauer therefore recommend this scheme of treatment as particularly applicable in private practice where conditions do not allow of local treatment (such as bladder wash-outs), and in children in whom a trial of conservative treatment is generally desirable. They add that it is important to recollect that a persistent pyuria may be secondary to tuberculosis, stone, or malformation.

40. Quinine Dihydrochloride in Chronic Constipation.

THE action of quinine and its official salts has been studied for many years, and Singer has reported the effects of the double salts in cases of severe and intractable constipation. Employing them subcutaneously, intravenously, and rectally in the form of suppositories and small enemas, he found that the rectal method gave by far the best and most prompt results. A. B. GRAHAM (*Journ. Amer. Med. Assoc.*, October 19th, 1929, p. 1187) records the results following the administration of 5-grain doses of quinine dihydrochloride as suppositories in 185 cases of chronic constipation of every type; good results were obtained in 76.2 per cent. of these patients. Though the improvement was not spectacular, Graham believes that, if a rapid evacuation of the contents of the rectum and pelvic colon is desired, the administration of these suppositories is far preferable to a cathartic or stimulating enema. Better and more prompt results will be obtained, and although the stools are large they are not watery. In 25 per cent. of the cases there was ano-rectal irritation, and in 2 per cent. small rectal haemorrhages occurred, but these were the only untoward effects manifested. Various theories have been advanced as to the mode of action of quinine on the intestine. Graham suggests that it is quite possible that this double salt of quinine, as Singer thought and Ladisch and Chione demonstrated, stimulates the smooth musculature of the intestine. Whether this is a direct action, or results from a mechanical and a possible chemical stimulation, could not be determined. In most cases in which positive results were not obtained with the 5-grain suppositories, doubling the dose proved successful; this might signify that some rectal mucosas require a more intense chemical stimulation than do others.

41. Treatment of Disseminated Sclerosis.

ADVOCATING haemolytic serotherapy in disseminated sclerosis, L. LAVASTINE and N. T. KORESSIOS (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, November 18th, 1929, p. 1255) refer to three cases reported in 1928; two patients have remained well for about three years, and in the third case the amelioration has persisted for a year. Four further cases are now recorded in which definite improvement followed injections of haemolytic serum. In a fifth patient doubt exists whether the remission was spontaneous or due to the treatment. In these cases two to five doses each of 1 to 5 c.cm. of the serum were administered. The authors state that in some cases a certain amount of improvement is obtained and the course of the disease seems to be arrested, but the persistence of Babinski's sign (as in one of the earlier reported cases) indicates that some lesions are irremediable, and that neither the intensity nor the duration of treatment can produce a greater improvement or definite cure. In disseminated scleroses of a paraplegic type with abolition or very great diminution of the muscular force, and even in those forms with a very marked cerebellar syndrome and conservation of the muscular force this treatment is useless. Serotherapy is recommended in all commencing cases in the first six or twelve months of their course; in acute cerebellar syndromes; in subacute sclerous myelites with a predominance of cerebellar troubles; and in paretic syndromes of slow evolution.

42. Antigangrene Serum in Typhoid Fever.

M. TAPIA and P. AZNAR (*La med. Ibera*, October 26th, 1929, p. 405) record eleven illustrative cases, in patients aged from 10 to 34, showing that the course of typhoid fever is in no way affected by antigangrene serum as recommended by Weinborg, owing to the association of anaerobic organisms, especially *B. perfringens*, with the typhoid bacillus. The authors agree that it is true that the patients' faeces always

contained *B. perfringens*, but this is also true of the faeces in other diseases or in normal health. They did not find any relation between the abundance of *B. perfringens* and its pathogenic action; in other words, the local conditions which might favour its multiplication did not appear to affect its virulence. There also did not appear to be any relation between the pathogenicity of the organism isolated from the patient and the toxic symptoms, or intestinal manifestations, in the patient.

43. Preservation of Typhoid and Cholera Vaccine.

F. KONRICH (*Zentralbl. f. Bakt.*, October 31st, 1929, p. 420), as the result of experiments on rabbits and guinea-pigs, comes to the conclusion that typhoid and cholera vaccine retain their efficacy for a considerably longer period than is generally supposed, the extreme limit being about two years. The ordinary room temperature does not have such an injurious effect on them as has hitherto been believed; it is best, however, to keep them in the ice-chest. The agglutination test is a less decisive means of deciding the efficacy of the vaccines than the immunity test.

Dermatology.

44. Alopecia Areata.

W. H. BROWN (*Brit. Journ. Derm. and Syph.*, August-September, 1929, p. 299) discusses the etiology of alopecia areata and its relation to vitiligo and possibly scleroderma, with references to the literature, his own observations, and a survey of 300 cases. The incidence is heaviest in the first decade of life, above all in the dark-haired. Among his own patients females predominated, though four other observers give a higher incidence in males. Family predisposition is also an important factor, though family traits may be quite easily overlooked except after searching inquiry. No one etiological factor will explain all cases, various factors, either singly or in combination, being responsible—as, for example, physical trauma, or psychic or mental stress and strain from anxiety, emotion, fever, and overwork. Such influences act by transmitting abnormal impulses through the sympathetic or endocrine-sympathetic system to the hair papillae with a disturbance of nutrition; they may be sudden and severe in onset or milder and more prolonged in operation. The absorption of toxins acting directly on the nutrition of the hair, or through the endocrine-sympathetic system from prolonged poisoning, may be a causative factor arising from focal sepsis, especially infection in the tonsils, teeth, nasopharynx, etc. Whatever the apparent causal factor, the brunt of the reaction in most cases is borne by the endocrine system, a primary lesion of which may so alter the normal hormone content of the blood as to disturb the nutrition of the hair, with resulting alopecia. Other factors are disturbances of the endocrine and vegetative nervous system, and a prominent predisposing factor is constitutional emotional instability.

45. Skin Changes in Pulmonary Tuberculosis.

J. SZÁNTÓ (*Derm. Woch.*, November 30th, 1929, p. 1839) finds that careful examination of the skin in patients suffering from pulmonary tuberculosis reveals two remarkable facts: (1) tuberculous lesions of the skin and oral mucosa seldom accompany pulmonary tuberculosis; (2) how frequently non-tuberculous skin lesions are found. Skin diseases occurring during the course of pulmonary tuberculosis may be tuberculides, or accidental dermatoses, but there is a group of dermatoses the connexion of which with tuberculosis is a moot point. Szántó found 1,405 cases of skin disease (that is, 29.53 per cent.) among 4,757 patients in two sanatoriums; of these, 601 patients were men, 793 women, and 11 children. These figures represent the total incidence of skin diseases, and not the number of patients affected; some had two or three dermatoses simultaneously. The group representing various tuberculides numbered only 38 (0.79 per cent.). These statistics approximate closely those of many other German writers. Sternberg suggests that there is an embryological antagonism between tuberculides and pulmonary tuberculosis, the skin being of ectodermal origin, while the lungs are chiefly derived from the endoderm; hence, coincident infection of skin and lungs occurs rarely. On the other hand, while in Czechoslovakia investigators have found only 20 per cent. of patients suffering from pulmonary tuberculosis and lupus, there occurred in Pomerania 24.7 per cent.; in Oslo 29.56 per cent.; in Theiss (Hungary) 34.8 per cent.; in Budapest 75 per cent.; and in Leningrad 78 per cent. These great differences discovered by various writers are due probably to geographical and ethnographical conditions. In the second group the present author places dermatoses of toxic origin. The septic condition of the skin lowers its resistance, hence the relative frequency of various forms of dermatitis and of eczema. Szántó found 103 cases of dermatitis and 71 of eczema among his patients. The sex incidence was practically equal. In the third group (usually associated with chronic febrile conditions) are skin oedema, dryness, atrophy, etc. The author places in a fourth group "indirect" skin lesions, such as seborrhoea, acne vulgaris, chloasma, acrocyanosis, and erythrocyanosis cruris. Chloasma phthisicorium must not be confused with Addison's disease; the former occurs on the exposed skin around the mouth, spreading later to the temporal and zygomatic regions; and the mucosae are not pigmented. Szántó places in a fifth group various dermatophyses and syphilis, found in 96 men and 35 women (2.75 per cent.). There has been a definite increase in syphilitic cases in the author's sanatoriums since 1925. Szántó found that the number of cases of erythema nodosum, lupus erythematosus, psoriasis, and herpes zoster was so small (the total number was only 30) that any connexion of these diseases with tuberculosis can be excluded.

46. Genital Moniliasis.

H. ODLAND and RACHEL E. HOFFSTADT (*Arch. Derm. and Syph.*, September, 1929, p. 335) record two unusual cases of an eruption on the genitals which was suspected at first of having a venereal etiology. A man complained of itching of the penis of four days' duration; a thin, fairly adherent, scaling band was found on the corona glandis, which on microscopical examination showed mycelial threads and clusters of conidia. His wife complained of a pruritus of ten days' duration; there was a thrush-like eruption of thick membranous patches on the labia minora, extending inwardly to the vaginal walls. Scrapings gave the same microscopic result as in the man. Complete cure resulted from the application of gentian violet alternated with a 10 per cent. solution of silver nitrate. No lesions were observed in the mouth or on any cutaneous surface. The cultural characteristics of the organism resembled those of the *Monilia pinoyi* of Castellani, except that it rendered milk alkaline after three weeks; the same type of organism has been reported by Castellani in a case of vaginal moniliasis. The thrush-like appearance of the eruption, especially in the woman, with its sharply marginated, pearly white, and thick membranous plaques, was characteristic; and the large numbers of mycelial threads and conidia were diagnostic. The disease appears to have been directly transmitted from the wife to the husband, the *Monilia pinoyi* being the causative agent in both cases.

Obstetrics and Gynaecology.

47. Section of the Ovarian Nerve Supply.

R. DUPONT (*Le Scalpel*, November 16th, 1929, p. 1245) has verified his opinion, shared with Lhermitte in 1927, that by cutting the nerve supply to the ovary there exists a simple remedy for a certain number of pelvic disorders. The nerves of the ovary take origin in the renal plexus, which is formed from the coeliac plexus; they then descend along the utero-ovarian artery, receiving several branches from the intermesenteric, and finally two or three nerves penetrate the ovary at the hilum. Hovelacque, who studied these nerves in detail, found no anastomosis between the nerves of the ovary and those of the uterus. In view of the derivation of the ovarian nerves, it becomes obvious that gastric and intestinal disorders may be associated with ovarian pain. The nerves entering the hilum are not visible to the naked eye, but their position has been determined by the author by means of a series of sections. He observed that they were constantly found at the middle of the hilum. The indications for the operation of cutting the ovarian nerve supply fall into three chief groups. The first is dysmenorrhoea of ovarian origin, the symptoms of which consist of lateral pain, which precedes and ceases with the appearance of the menses. This pain radiates to the thighs, and is accompanied also by distant manifestations such as digestive troubles. On examination of such a patient between the attacks of pain one or both ovaries are found to be enlarged and tender, and sometimes displaced. The second group of indications is furnished by subjective symptoms such as melancholy, neurasthenia, migraine, and insomnia. In the third group the symptoms are chiefly associated with the digestive tract, particularly with colic. The connexion between these groups of symptoms and the ovary is not always easy to demonstrate, but in the author's opinion the results of the operation verify the hypothesis. With a certain number of cases the section of ovarian nerves has been associated with ligamentopexy, resection of parts of ovary, and appendicectomy. But it is in the patients on whom ovarian neurectomy alone has been performed that the results have appeared convincing. The author supports his argument by quoting fifteen cases.

48. The Zondek-Aschheim Test for Pregnancy.

F. VOZZA (*Ann. di Ostet. e Ginecol.*, October 31st, 1929, p. 1189) confirms the value of the Zondek-Aschheim test for pregnancy, which consists in the injection into immature mice of the urine from the patient, a positive result being shown by increase in size and vascularity of the whole of the genital tract, and maturation of ovarian follicles with luteinization and intrafollicular haemorrhages. A slightly modified technique is described. In common with other observers, Vozza noted a comparatively large mortality (11 per cent.) among the animals used. In certain cases he claims to have obtained reliable results also from injection of the blood serum in amounts of 0.3 to 0.45 c.cm. The urine of 101 pregnant patients, of whom 49 were in the second month and 31 in the third month, gave positive tests in all but two cases; in one instance the reaction was positive eight days after the first menstruation had been missed. Ten cases of extrauterine pregnancy gave six positive and four negative results; in the former group the ovum was still alive, in the latter it had been destroyed by haemorrhage, etc. The reaction was positive in six cases of vesicular mole in which no foetal remnants were perceptible—a finding which has been made by others also; this is taken to signify that overproduction of the anterior pituitary hormone is due to a hormonic stimulus derived not from the foetus but from the chorion. Tests of the urine of 15 men, 15 patients with adnexal inflammation, and 20 other gynaecological patients were negative in all but one instance.

49. Alleviation of Labour Pains.

H. NEVINNY (*Wien. klin. Woch.*, November 7th, 1929, p. 1440) refers to the article by Vogt (see *Epitome*, 1928, vol., i, para. 329) and analyses the results obtained by the administration of pernocton in 100 deliveries accompanied by severe labour pains. The drug, which is a 10 per cent. solution of a barbituric acid derivative, was given intravenously after the commencement of a pain, the dose being 1 c.cm. of the solution to 12.5 kilos of body weight; by slowing the rate of injection to two minutes for 1 c.cm. the symptoms of excitement and restlessness, which were observed in some other cases, were lessened or removed. The shortest action of the drug lasted half an hour, and in those patients who had not received the full dose it lasted on an average 1½ hours. Of the 100 patients 71 had complete unconsciousness and 22 almost complete unconsciousness throughout the labour; in one case no result followed the injection, and in six the reaction was unsatisfactory owing to error in dose or in the selection of the site of the injection. In the majority of cases there was a marked fall in the maximum blood pressure after the injection, especially in patients with high blood pressure. The beneficial effect of pernocton on pre-eclamptic conditions has also been described by other observers. The respiration was deepened but not prolonged, resembling that of physiological sleep, and the pulse was slightly slowed. No unfavourable symptoms were noted either in the mothers or the children during their stay in the clinic.

Pathology.

50. Etiological Factors in Diabetes Insipidus.

L. D'ANTONA and L. CROSETTI (*Arch. Path. e Clin. Med.*, October, 1929, p. 3) have investigated three cases of diabetes insipidus, one of which was post-encephalitic, one probably of arterio-sclerotic origin, and the third of no obvious assignable etiology. In no instance were there any changes in the sella turcica to be noted radiologically. In all three cases pituitrin gave a marked inhibition of the diuresis, but this was only of short duration and without effect on the specific gravity of the urine. The authors regard the action of pituitrin as purely vaso-constrictor. They find that ergotamine can diminish the antidiuretic action of pituitrin; a similar antagonistic effect which has been noted for these substances in respect to heat production seems to confirm the hypothesis that pituitrin acts by way of the diencephalic centres. It was found that whereas potassium chloride combined with pituitrin does not modify appreciably the action of pituitrin, the combination of calcium chloride and pituitrin not only intensifies the antidiuretic action, but increases the density of the urine. The authors have studied in detail the elimination of the radicles Cl, SO_4, P_2O_5, K, Ca, and Na, and note that in diabetes insipidus there is an alteration in the elimination of different ions, which are concentrated in varying degree, not only in different cases, but in the same case, depending on the introduction of different chemical combinations of the same ion. This is an indication that the polyuria of diabetes insipidus should not be regarded as a simple renal hydrorrhoea, but that, besides the kidney, the tissues play an important part in the phenomenon.

51. The Nasopharyngeal Flora in Health and during Respiratory Disease.

E. L. BURKY and W. G. SMILLIE (*Journ. Exper. Med.*, November, 1929, p. 643) have conducted an investigation of the nasopharyngeal flora in isolated communities in Alabama and Labrador. In Alabama cultures were taken at irregular intervals from a group of twenty-three school children; in Labrador most of the cultures appear to have been taken from native trappers. During the investigation in Alabama an epidemic of colds broke out, and in Labrador an epidemic of tracheitis, which was apparently of influenzal origin. Though both qualitative and quantitative differences were found, there was a considerable degree of parallelism between the results in the two communities. The normal flora consisted mainly of Gram-negative cocci, haemolytic streptococci, and staphylococci; in Labrador pneumococci were common, whereas in Alabama they were absent; Pfeiffer's bacillus was present in only small numbers. During the epidemic of colds in Alabama the most striking finding was the appearance of pneumococci and the rise in the incidence of Pfeiffer's bacillus; haemolytic streptococci likewise appeared, but only in small numbers. During the epidemic of tracheitis in Labrador Pfeiffer's bacillus increased in incidence, but the percentage of pneumococci actually fell slightly; haemolytic streptococci were practically absent. It is noteworthy that in Alabama the prevalence of Pfeiffer's bacillus reached its maximum a month after the epidemic of colds had reached its height, whereas in Labrador the maximum prevalence was coincident with the rise of the tracheit's outbreak. The results obtained in these two isolated communities are in general agreement with those obtained by Park in New York.

52. Cultivation of the Leprosy Bacillus.

K. SHIGA (*Zentralbl. f. Bakt.*, November 30th, 1929, p. 511) claims to have cultivated the leprosy bacillus on an artificial medium. The technique used was as follows. The lepra nodules were excised under antiseptic conditions and sent to the laboratory, where they were examined three to ten days after excision. The nodule was ground up in a mortar with 5 per cent. sulphuric acid; it was left in the incubator for twenty minutes, and was then centrifuged. The deposit was washed with saline solution and again centrifuged. The washed deposit was inoculated with a platinum loop on to glycerin potato, prepared by steaming the potato wedges in 4 per cent. glycerin broth, standardizing the reaction to *p*H 6.8 to 7.0, transferring the wedges to Roux tubes, the lower part of each of which was filled with glycerin broth, and sterilizing the medium in the autoclave. No growth is detectable at 37° C. for about two months, and even then no visible colonies appear. The colonies that do form are very delicate and effuse, and under the microscope are found to be about 0.02 to 0.1 mm. in diameter. Films made after two months, and stained by the Ziehl-Neelsen method, show the bacilli arranged chiefly in clumps, similar to the arrangement in the tissues. They withstand 2 per cent. acid-alcohol; whether higher strengths are tolerated without decolorization is not stated. Subcultures are made every two months, and, since the colonies on potato are invisible, several tubes should be inoculated in case the platinum loop fails to touch a colony. The organisms have now been cultivated for four generations on this medium. On glycerin agar very tiny, just visible colonies have been obtained. The author attributes his success chiefly to the treatment of the lepra nodules with sulphuric acid.

53. Storage of Vitamins in the Placenta.

H. GUGGISBERG (*Deut. med. Woch.*, November 22nd, 1929, p. 1953) has shown by experiments on rats that the human placenta serves as a store for vitamins. The placenta can deprive a mother already deficient in vitamins for the advantage of the foetus; the mother becomes ill, but the foetus remains healthy, though the reserve store of vitamins in the offspring is reduced, and the resistance to extrauterine influences is lowered. While the general characteristics of the foetus, its size, weight, and the development of its bones and organs are not affected, the richness in vitamins and the mineral metabolism of the offspring are influenced by the placenta. From observations on human beings and on rats Guggisberg found that by giving extra vitamin with the food to the pregnant mother the vitamin strength of the offspring was raised. To the food of a series of pregnant rats several drops of a vitamin preparation were added daily. After birth the young received mother's milk for seven weeks, and then this was substituted by McCollum's rachitic diet; none of these young rats developed rickets. A number of control young rats born from normally fed mothers who had not received the vitamin preparation were similarly fed, first on mother's milk and after seven weeks on McCollum's diet; all these rats without exception developed rickets.

*"Ordinary milk sold throughout the greater part of the year contains almost no anti-rachitic vitamin" (*The Lancet*, 23 11 29.)

Since raw milk is practically devoid of Vitamin D (the anti-rachitic vitamin), any food made from it must suffer from one or more of certain defects.

AN INFANT FOOD NOT CONTAINING ADDED VITAMIN D MUST NECESSARILY—

1 be very deficient or altogether lacking in this vital constituent, and thus endanger bone formation and dentition, as well as general development.

or

2 contain an excess of added fat to make good the vitamin that the milk lacks. In this case fatty stools result, with excretion of the calcium actually required for growth and development.

Eighteen months' results in practice now confirm that Sunshine Glaxo, with its added "Ostelin" Vitamin D, gives firm flesh, sound bone, good teeth, and causes no digestive disturbance.

SUNSHINE GLAXO

is pure milk, fully humanised and with "Ostelin" Vitamin D added under carefully controlled conditions, in a definite quantity which has been determined by more than two years' clinical experience.

A trial supply gladly sent on request to—

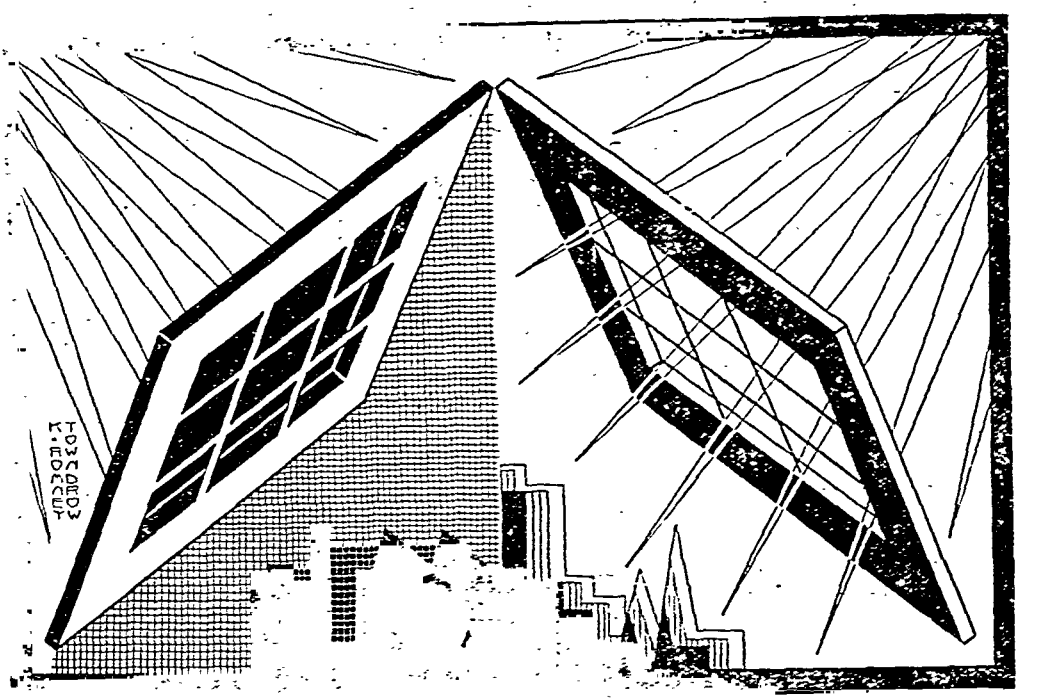
(Underground Station—Tottenham Court Road)

where qualified female Fitters are always in attendance and the services of an Orthopædic Mechanist are available each Wednesday. Appointments should always be made.

It is hardly necessary to emphasize the advantages of being able to send a patient to be fitted by Surgical Experts for the exact type of appliance prescribed.



N B.—The requirements of Provincial Medical Men are equally catered for by our various Depots and Fitting Rooms in other parts of the country.

All correspondence (excepting regarding Appointments) should be addressed to Birmingham.

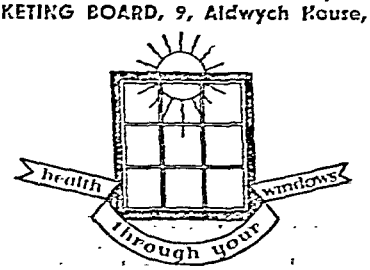
WINDOW HYGIENE IN CITIES

Permanent inlet for ultra-violet rays created by "Vita" Glass

Natural ultra-violet radiation is available in cities and in the smoke-charged atmosphere of industrial localities. Recent research has afforded unimpeachable evidence that an appreciable amount of ultra-violet light penetrates to such areas, but it is shut out of city buildings by windows of ordinary glass.



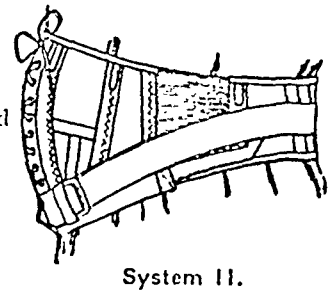
"Vita" Glass renders every window that receives direct daylight permanently hygienic, whether the window faces North, South, East or West, in Summer or Winter.

"Vita" Glass creates in perpetuity an inlet for the ultra-violet rays, and can prove of great assistance to the practitioner in the treatment of patients who cannot be moved out of doors.

The installation of "Vita" Glass is not a costly matter to-day. For instance, a bay-window of average size can be fitted with "Vita" Glass for 38/-, plus the cost of fixing.

Further information about "Vita" Glass will be sent to any Medical man who is interested. Write to: "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.



"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

Domen Belts

Experienced Fitters.

Private Fitting Rooms.

System II.

BELT FOR GENERAL SUPPORT.

Pre-eminently useful after confinement, affording the most effectual support to the internal organs, preventing pressure on the fundus of the womb.

System II should be used in all cases where the abdominal muscles need support. It also invariably gives good results in cases of enteroptosis, gastroptosis, and all similar troubles.

Write or 'Phone for Catalogue.

JAEGER
Pure Wool

K K UNDERWEAR.

Even Medical Men do get Colds.

That is why Jaeger, with its special health-preserving properties, appeals to the Profession. There are many excellent varieties of Jaeger Underwear, but KK is particularly mentioned as being most suitable. The weight, for instance, is medium; it has been carefully chosen and does not vary, which is a vital consideration; while the wool, which is wonderfully soft and gives real comfort, is also hard-wearing.

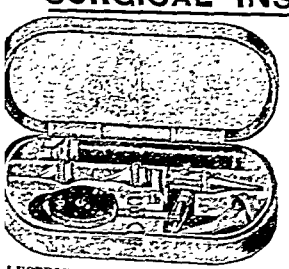
THE CURTIS ABDOMINAL SUPPORT
MODEL No 1
FOR EFFICIENCY

The principle of the Curtis Abdominal Support, Model No. 1, is based on a direct anterior posterior pressure, a principle which affords very considerable advantages over any abdominal belt or support yet available.
The only support giving direct abdominal uplift; there is no cramping or binding of the hips, whilst a constant uplifting pressure is maintained in any assumed position. There are no complicated fastenings; one strap and buckle suffices.
Made of metal, it has a much longer life without being heavier.



For full particulars apply to:—

FOR DEAFNESS
Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE. *Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.*

MEDICAL REPORTS. *Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.*

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

Applications are invited for the post of ASSISTANT ANÆSTHETIST (woman) at the above Hospital of 25 beds. The appointment will be for a period of six months in the first instance, from March 1st.

Applications, with copies of three recent testimonials, to be sent to the Secretary, The Marie Curie Hospital, 2, Fitzjohn's Avenue, London, N.W.3, not later than Saturday, February 1st. Further particulars may be obtained from the Secretary.

Coventry and Warwickshire HOSPITAL, COVENTRY. (307 Beds.)

RESIDENT ASSISTANT HOUSE SURGEON (male) wanted. Salary £125 per annum, board, laundry, and attendance provided. Candidate must be duly qualified and registered.

Applications, stating age, and enclosing copies of recent testimonials, should be sent to the undersigned on or before January 21st.

(Miss) R. HOOPER, Secretary.

Nottinghamshire County Council

APPOINTMENT OF SCHOOL DENTISTS.

Applications are invited for the appointment of four additional whole-time School Dentists at a salary of £500 per annum, rising after two years' satisfactory service by increments of £25 to a maximum of £550. Travelling expenses will be paid in addition according to the scale approved by the County Council.

Candidates must be fully qualified and registered dentists, and the persons appointed will be required to perform such duties as may be from time to time prescribed by the County Education Committee and to devote their whole time to the duties of the office. They will be members of the staff and act under the control and direction of the County Medical Officer of Health, and required to reside in a part of the County to be approved by the Education Committee.

The appointments will be terminable by three months' notice on either side.

Successful candidates will be required to pass a medical examination.

Applications on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to "The County Medical Officer, Shire Hall, Nottingham," not later than January 22nd.

Shire Hall, Nottingham. K. TWEEDALE MEABY, Clerk of the County Council.

Somerset County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER.

Candidates must possess a Diploma in Public Health and have had experience of the general administration of a Public Health Department, of School Medical Inspection work and its administration, and of Mental Deficiency work. Experience in the treatment of venereal diseases under modern methods is also necessary.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the County Medical Officer of Health and will carry out such duties as the County Council may assign to him from time to time.

The salary will be at the rate of £750 per annum, rising by annual increments of £25 to a maximum of £900.

The appointment will be made subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922. Office and travelling expenses will be provided. Particulars as to the terms of the appointment, duties, qualifications, etc., may be obtained from the undersigned.

Applications, stating age, qualifications, and previous experience, together with copies of not more than three recent testimonials, to be forwarded to me not later than January 16th.

Personal canvassing will be a disqualification.

County Health Dept., Boulevard, Weston-super-Mare. W. G. SAVAGE, County Medical Officer of Health.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (man or woman) in its Mental Hospital Service. Candidates must be under 35 years of age and be registered to practise both in Medicine and Surgery in England. Salary £300 a year, rising by annual increments of £25 to £400 a year, plus fluctuating temporary additions, the present total commencing remuneration being approximately £423 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. weekly), if required to be resident. In the case of women, marriage terminates contract of service. Candidate appointed will be *pensionable under the* Asylums Officers Superannuation Act, 1909. Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Completed applications must be received by Thursday, January 16th.

Canvassing disqualifies.

MONTAGU H. COX, Clerk of the London County Council.

David Lewis Northern Hospital.

RESIDENT MEDICAL OFFICERS.

Applications are invited for the following:
FOUR HOUSE SURGEONS;
TWO HOUSE PHYSICIANS;
to commence duties from April 1st.

Remuneration at the rate of £100 per annum, with board-residence.

Applications and testimonials to be in the hands of the undersigned on or before Saturday, January 18th.

H. LEVEY, Secretary-Supt.

Nottinghamshire County Council

TUBERCULOSIS OFFICER.

Applications are invited for the appointment of Tuberculosis Officer at a salary of £750 per annum, with travelling expenses according to the Scale approved by the County Council.

Candidates must be fully qualified and registered Medical Practitioners, with special experience in the diagnosis and treatment of tuberculosis, and should have held resident House appointments in a General Hospital for at least six months after graduation. The possession of a Diploma in Public Health is desirable.

The person appointed will be required to take *charge of County Dispensaries and to perform* such other duties as may be prescribed from time to time. He will be a member of the Staff and act under the control and direction of the County Medical Officer of Health, and will be required to devote his whole time to the duties of the office and to reside in such part of the County as may be approved.

The appointment will be terminable by three months' notice on either side, and the successful candidate will be required to pass a medical examination.

Applications, on the prescribed form (which may be obtained from me), accompanied by copies of not more than three recent testimonials, should be forwarded to the County Medical Officer, Shire Hall, Nottingham, not later than January 18th.

K. TWEEDALE MEABY, Clerk of the Nottinghamshire County Council.

City of Norwich.

ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER. He will be required to reside and carry out the duties at the Isolation Hospital, to devote his whole time to the services of the Council and not to engage in any private practice. Salary £450 per annum, with rooms, board, attendance, and washing (emoluments valued at £150 per annum). Board allowance at the rate of £60 per annum allowed when absent from Hospital on leave.

Candidates must possess a Diploma in Public Health. The officer selected will be under the direction and supervision of the Medical Officer of Health, who is also the School Medical Officer. He will be required to undertake any medical duties of the Public Health Department, including work under the School Medical Service, and the Maternity and Child Welfare Scheme. Age not to exceed 40.

The appointment will be subject to three calendar months' notice on either side and to the terms and conditions of the Local Government and Other Officers Superannuation Act, 1922, and the successful candidate will be required to furnish a medical certificate of fitness.

Applications, stating age, qualifications, experience, and when at liberty, accompanied by copies of not more than three recent testimonials, must be sent on or before Jan. 16th.

Canvassing, directly or indirectly, is prohibited and will disqualify.

Churchman House, Norwich. V. F. SOOTHILL, M.A., M.D.

City of Sheffield.

ASSISTANT TUBERCULOSIS OFFICER.

Wanted, a male (unmarried) Assistant Tuberculosis Officer, to reside at WINTER STREET HOSPITAL, and to devote his whole time to the Municipal Tuberculosis Scheme.

Salary £450 per annum, rising to £500 per annum by annual increments of £25, with board, residence, and laundry.

Applicants must be registered Medical Practitioners, with not less than three years' experience.

Applications, stating age, qualifications, and experience, with *copies of testimonials*, to be sent to the undersigned on or before Jan. 18th.

Town Hall, Sheffield. FRED. E. WYNNE, Medical Officer of Health.

City of Birmingham.

The Public Health Committee invite applications from Medical Women for the post of MEDICAL OFFICER for Maternity and Child Welfare. Applicants must have had Children's Hospital and Maternity Hospital experience. The Diploma of Public Health is desirable. Salary £600 per annum. The candidate appointed will be required to join the Birmingham *Corporation Superannuation Scheme*, and for this purpose to pass a medical examination. The appointment will be terminable by one month's notice on either side. Applications, endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, Council House, Birmingham, and returned to him on or *before* January 20th. Canvassing will disqualify.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

GYNÆCOLOGIST AND OBSTETRICIAN.

Applications are invited from fully qualified Medical Practitioners for the above appointment.

The Hospital accommodation is fixed by the Guardians at 926, divided into Medical, Surgical, Children's, Infectious, Gynæcological, and Obstetrical Sections. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments.

Candidates for the appointment must have had *previous hospital experience of a similar nature* and be Fellows of the Royal College of Surgeons, England.

The scale of salary will be £700, rising by annual increments of £50 to a maximum of £1,000 per annum, and the salary of the successful candidate will be fixed within the scale according to experience and qualifications. Furnished quarters, rations, laundry, and attendance will be provided by the Guardians. Alternatively, a cash allowance will be paid if the officer appointed is non-resident. A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896.

The officer appointed will be required to assist in the training and lecturing of nurses, and, should occasion arise, to attend at any of the other Institutions under the control of the Guardians.

Further particulars of the appointment may be obtained from the Guardians' Chief Medical Officer, F. W. ELLIS, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than 11 a.m. on Wednesday, January 15th.

Union Offices, Edmund St., Birmingham. C. P. BEECH, Clerk to the Guardians.

Metropolitan Borough of SOUTHWARK.

LADY ASSISTANT MEDICAL OFFICER OF HEALTH.

The Southwark Borough Council invite applications for the position of Lady Assistant Medical Officer of Health. Applicants must be between 25 and 35 years of age, unmarried, and must be fully qualified and registered Medical Practitioners. It will be a condition of appointment that, in the event of the marriage of the person appointed, she immediately resign her position under the Council.

The principal duties of the officer appointed will be in connection with Maternity and Child Welfare work. She will be required to possess a practical knowledge of ante-natal and post-natal diseases and management of women, and the developmental treatment of children and their diseases. She will be required to reside in or near the Borough, and must give her whole time to the duties of the office, acting under the direction of the Maternity and Child *Welfare Committee of the Council* and the Medical Officer of Health.

Special consideration will be given to applicants who have held official positions in hospitals or other institutions for the treatment of women and children.

The salary will be £600 per annum, inclusive, and the appointment will be subject to the approval of the Ministry of Health, and to three months' notice to terminate the engagement on either side.

The selected applicant will be required to pass the medical examination specified by the Council, and will be subject to the provisions of the Council's Superannuation Scheme.

Forms of application, containing a list of duties and conditions of appointment, may be obtained on sending a stamped addressed envelope to the undersigned. Applications, on the prescribed form, accompanied by copies of three recent testimonials, and endorsed "Lady Assistant Medical Officer of Health," must be received by me not later than noon on Wednesday, January 22nd.

Canvassing, directly or indirectly, will disqualify.

DAVID T. GRIFFITHS, Town Clerk.
Southwark Town Hall.
Walworth Road, S.E.17.
January 1st, 1930.

St. John's Hospital, Lewisham, S.E.13.

There is a vacancy for a RESIDENT MALE CASUALTY OFFICER. Salary £100 p.a. The appointment is for three months. Applications, with copies of testimonials, should be sent to the Secretary of the Hospital as soon as possible. The successful applicant should be prepared to begin duty at once.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in January, 1930. Applications should reach the War Office not later than January 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January. They must be under 28 years of age on February 1st, 1930, and registered under the Medical Acts.

Officers of the R.A.M.C. are liable to serve in any part of the world where British Troops are quartered.

Ample opportunities exist in the Army for clinical professional work, both Medical and Surgical, as well as for the study and practice of Hygiene, Pathology, and all the special branches.

The cost of Post-Graduate study, which is compulsory, is met from Army Funds.

Pay and Allowances.—Pay from £500 to £2,000 a year according to rank and length of service.

Gratuities on Retirement.—After 7 years' service £1,000.
„ 15 „ „ £2,800.
„ 18 „ „ £3,500.

Current rates of retired pay range from £372 per annum, normally earned by a Major after 20 years' service, to £940 per annum, the maximum for which a Major-General is eligible. The rates of pay and retired pay are subject to periodical variation consequent on fluctuation in the cost of living.

Outfit Grant.—An officer on joining receives £50 as outfit allowance.

Marriage Allowance.—Officers of 30 years of age and over who are married are entitled to draw special rates of allowances.

A Voluntary Widows' and Orphans' Fund exists for officers of the Corps.

A certain number of temporary Commissions will also be offered at the same time under the same conditions as regards age and qualifications as those required of candidates for permanent Commissions.

All particulars may be obtained by application, in writing or personally, to the Under Secretary of State, The War Office (A.M.D.I), Whitehall, London, S.W.1.

INDIAN MEDICAL SERVICE

Recruitment of European Officers.

Applications are invited from medical men for permanent commissions in H.M.'s Indian Medical Service. The terms offered include a gratuity of £1,000 on retirement after six years' service, or £2,500 after 12 years' service, together with free return passages, for those who no longer desire to remain in the Service In other respects the terms will be as detailed below.

Candidates must be British subjects under 32 years of age at the time of application, and must be registered under the Medical Acts in force in Great Britain and Northern Ireland.

CAREERS.

The Indian Medical Service offers wide opportunities of medical experience, including clinical, preventive, specialist, and research work. At the beginning of his career an officer is employed on the military side, which has medical charge of the Indian Army. Promotion is on a time scale up to the rank of Lieutenant-Colonel, and by selection to the ranks of Colonel and Major-General. An officer may apply after two years' Indian service for transfer to the civil side, from which appointments are made to Civil Surgeoncies, which are established at the principal civil centres to provide for the medical needs of civil officials and for general medical administrative purposes; to specialist (for example, public health and bacteriological) services; to research posts; and to professorships at the Medical Schools.

PAY.

The monthly rates of pay for European officers in the Service who have a "non-Asiatic" domicile are as follows:

Rank.	Service in Rank.	Basic Pay.	Overseas Pay.	Year of Total Service.
1	2	3	4	5
		Rs.	Rs.	
Lieut.		500	150	1st
			150	2nd
			150	3rd
Capt.	(i) During first 3 years' service as Captain	650	150	4th
			£15	5th
	(ii) With more than 3 and less than 6 yrs.' service as Captain	750	£15	6th
			£25	7th
			£25	8th
			£25	9th
	(iii) With more than 6 years' service as Captain	850	£25	10th
			£25	11th
			£25	12th
Major	(i) During first 3 years' service as Major	950		
	(ii) With more than 3 and less than 6 years' service as Major	1100		
	(iii) With more than 6 years' service as Major	1250		
Lieut.-Col.	(i) Until completion of 23 years' total service	1500	£30	13th and over
	(ii) During 24th and 25th years' service	1600		
	(iii) After completion of 25 years' total service	1700		
	(iv) When selected for increased pay	1850		

EXTRAS.—In addition to the above rates various allowances are admissible for a large number of special appointments on both the military and the civil side which may be held by members of the Indian Medical Service. Special high rates of pay are also attached to the numerous administrative appointments open to officers in both branches of the Service.

WAR SERVICE CONCESSIONS.

Any service rendered by an officer during the war as a medical or combatant officer, or in a position usually filled by an officer, may be counted as service for increments of pay, promotion, retirement and retired pay, but not for gratuity.

One half of any service in the ranks during the war may be counted as service for retirement and retired pay only.

OUTFIT ALLOWANCE.

Officers on appointment will receive an outfit allowance of £50.

PRIVATE PRACTICE.

With the exception of Administrative Officers, military or civil, and officers holding certain special appointments, officers are not debarred from taking private practice, so long as it does not interfere with their proper duties.

PENSIONS.

The rates of pension are as follows:

	Per annum.
	£
After 17 years' service for pension	400
,, 18 ,, ,, ,, ...	430
,, 19 ,, ,, ,, ...	460
,, 20 ,, ,, ,, ...	500
,, 21 ,, ,, ,, ...	540
,, 22 ,, ,, ,, ...	580
,, 23 ,, ,, ,, ...	620
,, 24 ,, ,, ,, ...	660
,, 25 ,, ,, ,, ...	700
,, 26 ,, ,, ,, ...	750
,, 27 ,, ,, ,, ...	800

These rates are subject to alteration on account of a rise or fall in the cost of living as compared with the year 1919 to an extent not exceeding 20 per cent. in all, the revision being undertaken triennially. With effect from July 1st, 1927, a reduction of 4½ per cent. has been made on this account from the amounts shown.

There are additional pensions ranging from £65 to £350 per annum for officers who have held administrative appointments.

PASSAGES.

An officer on appointment is provided with a free passage to India. The wives and families of officers who are married prior to the date of the officers' embarkation on first appointment will also be provided with free passage to India, subject to the payment of messing charges.

Officers and their families are also eligible for passage concessions under which they are granted a certain number of return passages home at Government expense during their service.

INSTRUCTION PRIOR TO EMBARKATION.

Officers are required to undergo courses of instruction at the Royal Army Medical College and at Aldershot, lasting approximately six months, prior to their embarkation for India on first appointment.

Full details regarding these appointments and forms of application may be obtained from the Under-Secretary of State for India, Military Department, India Office, London, S.W.1. Applications should be submitted as soon as possible. The Selection Committee will meet shortly to make nominations, and the selected candidates will be required to attend a course of instruction commencing on February 4th, 1930.

ROYAL ARMY MEDICAL CORPS.

TWENTY-FIVE permanent COMMISSIONS in the ROYAL ARMY MEDICAL CORPS will be offered in January, 1930. Applications should reach the War Office not later than January 20th.

Candidates will be selected for Commissions without competitive examination, and will be required to present themselves in London for interview and medical examination towards the end of January. They must be under 28 years of age on February 1st, 1930, and registered under the Medical Acts.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1782, 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

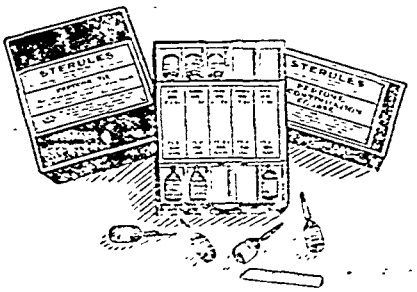
Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: TEMPLE BAR 1616 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES, who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).



No charge is made to Principals for the introduction of Locum Tenens or Assistants.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. SUSSEX.—Favourite Residential Town.—PARTNERSHIP with view to succession (3 to 4 years) can be acquired by preferably an Oxford or Cambridge Graduate about 30 to 35 years of age and fond of sport. Practice is old-established, chiefly better class, and the receipts last year amounted to over £2,500. Two-fifths share will be sold to commence with. Personal application desired if possible.
2. DEATH VACANCY.—NORTHANTS.—Near Large Town. Old-established country PRACTICE, producing about £1,200 p.a., including panel of 700-800. Fees 2/6 to 10/6, medicine extra. Mid. 2 to 5 gns.; about 20 cases yearly. Very good house available, or purchaser can choose his own residence. Prem £1,200. Locum in charge.
3. WITHIN 100 MILES OF LONDON.—PARTNERSHIP.—A share producing about £1,200 p.a., with prospects, is for disposal owing to retirement of one of the partners in an old-established Practice. Ingoing partner would reside in a pretty country district about 5 miles from pleasant country town, where main practice lies. No opposition. Total income about £8,000, including valuable appointments worth about £2,000, and panel. Very desirable residence (ample accommodation) with 2½ acres of ground available on lease at low rental of £60. Premium 2 years' purchase.
4. YORKS.—(North Riding.)—Country PRACTICE in beautiful district. Average income over £750, including panel of about 330. Fees 3/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
5. GLOS.—Favourite Town.—Mixed general non-dispensing PRACTICE. Income last year over £700, including panel of 550. Visits 3/6 to 10/6. Mid. 2 to 10 gns. Good house, in excellent position, with 10 bedrooms, 3 reception, 3 bedrooms, etc. Rent on lease £75 p.a. Premium 1½ years' purchase. Suitable lady doctor.
6. PARTNERSHIP.—COUNTY TOWN within easy reach of London.—A one-third share is offered, owing to retirement through ill health of one of two partners, in an old-established better and mixed-class Practice, averaging over £3,600 p.a., including panel of 1,100. Fees 3/6 to 42/-, medicine extra. Good house, with 3 reception, 6 bedrooms, etc. Garden. Rent on lease £85 p.a. Excellent society, sport, and schools. Prem. £2,700, to include share of surgery. Premium 1½ years' purchase.
7. LONDON, W.—Chiefly middle-class PRACTICE, averaging about £700 p.a., including panel of 750. Visits 3/6, 5/-. No midwifery. Suitable house, with 4 beds., etc. Rent on lease £96 p.a. Prem. £1,100.
8. MANCHESTER DISTRICT.—Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
9. NORTHANTS.—Unopposed old-established Country PRACTICE within easy reach of large town, worth last year over £1,500, including panel (with mileage) £675 and appts. about £80. Visits 5/- to 20/-, medicine sometimes extra. Suitable house available. Rent £70 p.a. Premium 1½ years' purchase. Held by Vendor (retiring) over 30 Years. Spot of all kinds.
10. SOUTHERN COUNTY.—PARTNERSHIP.—Third share of very old-established increasing Practice situated in a beautiful residential and agricultural district within 10 miles of the sea. Cash receipts last year over £3,000, including panel and appointments. Visits 5/- to 21/-. Suitable house can be arranged for ingoing partner. Prem. 2 years purchase. District is developing rapidly and offers good scope.
11. DEATH VACANCY.—NORTH WALES.—Easily worked PRACTICE, offering large scope, and situated in a beautiful seaside and country district. Cash receipts about £300-£900. Very convenient well situated house, or near offer. Efficient Locum in charge.
12. EASTERN COUNTIES.—LARGE TOWN.—Sound good middle and working-class PRACTICE, producing last year nearly £1,900, including panel of 2,300. Fees 3/6 to 10/6, medicine extra. No midwifery. Specially built house, easily run and with every modern convenience. Contains 2 reception, 5 to 6 bedrooms, etc., and good professional accommodation. Garage. Garden. Price for freehold £3,000, half on mortgage. Premium 1½ years' purchase.
13. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visit 5/- to 21/-. Panel of about 380. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' purchase.
14. PARTNERSHIP.—ESSEX.—(Within 50 mils of London).—Third Partner required in very old-established rapidly increasing Practice in small country town. Cash receipts for past three years average £4,176), including panel of 2,200 and appts. Third share is for disposal (opposition slight. Visits 5/- to 21/-. £3,755 (last year £4,176), including panel of 2,200 and appts. Good house, professional accommodation, 2 reception, 4 bedrooms, bathroom etc. Large garden. Garage. Rent £60. Premium 2 years' purchase. Educational facilities and sport.
15. WITHIN TWENTY MILES OF LONDON.—Old-established good mixed-class PRACTICE, in attractive residential district. Receipts average £1,000 p.a. Panel of nearly £500 and appts. worth £60. Visits 3/6 to 21/-. Very nice house, with all modern conveniences and half acre of garden. Price for freehold £1,800. Premium £1,400.
16. ESSEX.—(Within 15 miles of London.—Old-established unopposed and increasing PRACTICE, in pretty country district. Income last year £1,150, including Union £90 and panel £432. Comfortable house, with ample accommodation and large garden. Rent £70 p.a. on lease. Premium £1,650. Ill health reason for sale
17. HOME COUNTIES.—Within few miles of large town.—Old-established unopposed and increasing PRACTICE, in pleasant district, worth over £3,000 p.a., including panel, with mileage, producing about £1,000 and appts. £260. Visits 3/6 to 10/6, medicine usually extra. Very little midwifery. Good house (7 bedrooms, etc.), garden, garage. Price, freehold, £2,000. Premium 1½ years' purchase.
18. DEATH VACANCY.—NEAR MANCHESTER.—Old-established mid and working-class PRACTICE, producing last year at the rate of nearly £900 p.a., including panel of 550. Fees 3/- upwards. Specially built house in good position, with 2 reception, 6 bedrooms, etc., and large professional rooms, etc. Price £1,800, part on mortgage, or might be rented. Premium £800. Locum in charge.
19. CHESHIRE.—Industrial Town within easy reach of Manchester—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation, Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
20. ESSEX.—POPULAR COAST TOWN.—Small easily worked PRACTICE, offering good scope, as district developing. Income last year £550 Panel of 200. Fees 2/6 to 7/6. House contains 2 reception, 3 bedrooms, etc. Garden. For sale or on rental. Premium £750, part down and balance instalments.
21. DEATH VACANCY.—SOUTH WALES.—Seaside Resort.—Old-established mixed-class PRACTICE in favourite locality. Receipts for past 12 months £1,400, including panel of 607. Visits 3/6 to 21/-. Convenient house, with 2 reception, 4-6 bedrooms, and professional rooms, etc. Rent on lease £80 p.a. Good sport and schools. Prem. 1 year's purchase.
22. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,250, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,250, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.

Citronin

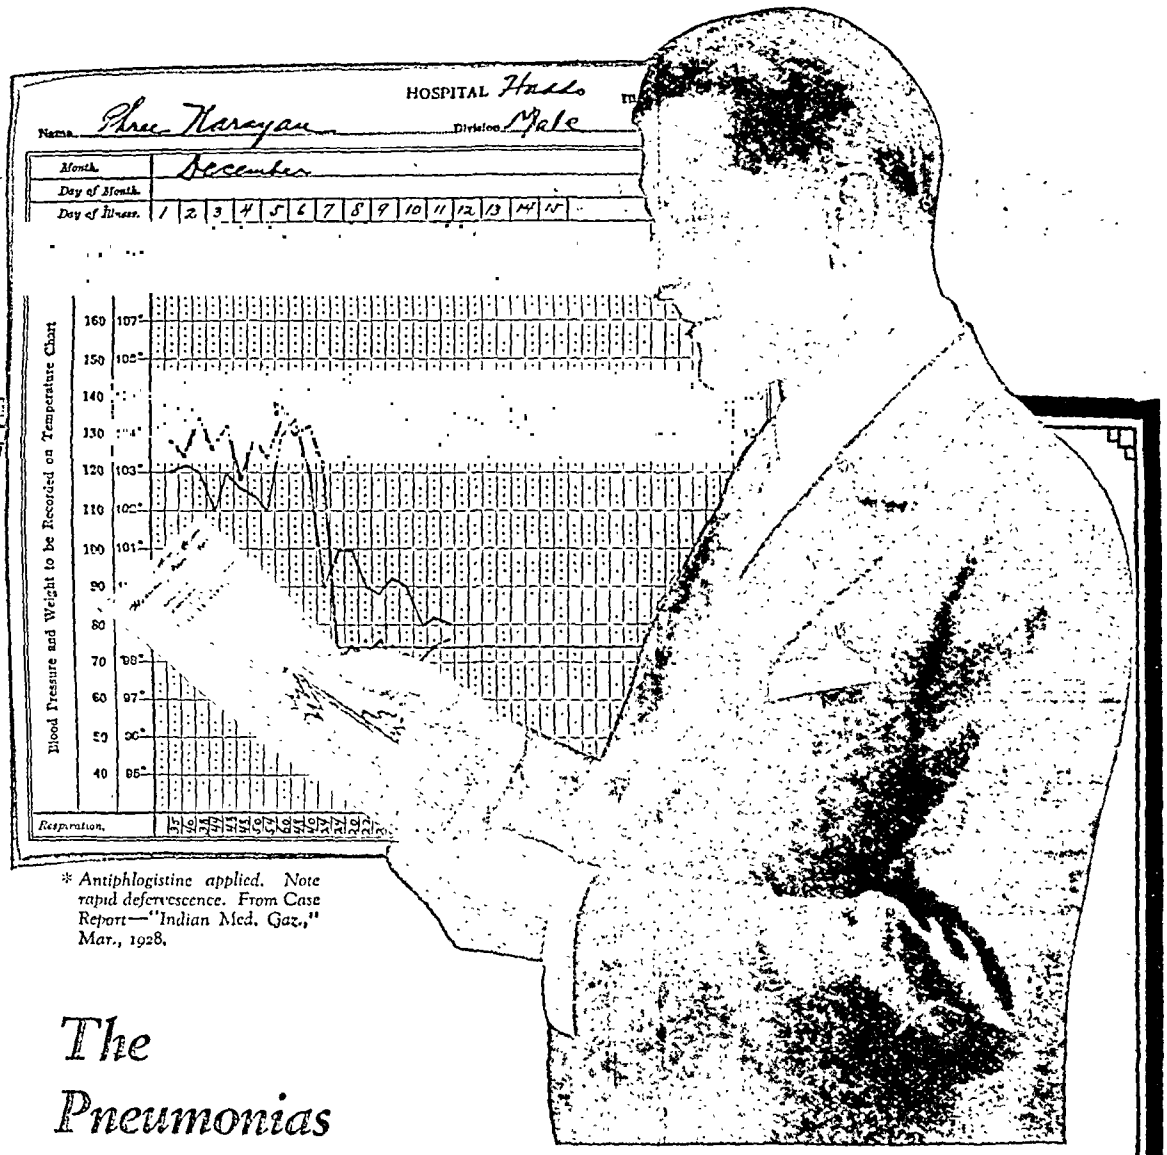
A New and Effective Preparation for Alleviating Cough.

CITRONIN is a beautifully clear, cherry-red liquid with an agreeable aromatic fruity odour. It is not a "syrup."

The potassium guaiacol sulphonate in this preparation has a definite germicidal action and it possesses the advantage of not disturbing the digestion as other guaiacol salts do. The sodium citrate and citric acid stimulate bronchial secretion and also aid in liquefying the secretions thus formed. The action of ipecacuanha is well known, as is also that of ethylmorphine. Cascara Evacuant has been incorporated for its eliminative and intestinal tonic effects.

Bronchitis, subacute or chronic, suggests the use of Citronin, in which conditions it can be expected to loosen the dry cough within a short time. For adults the dose of Citronin recommended is one or two teaspoonfuls at intervals of not less than three or four hours.

Each fluid drachm of Citronin represents:—

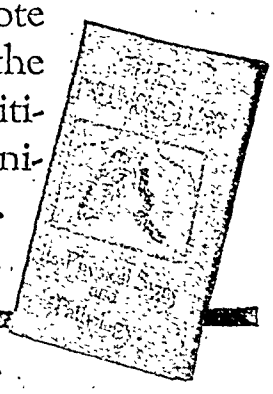


Potassium Guaiacol Sulphonate	1 grain
Sodium Citrate	2-1/2 grains
Citric Acid	1/2 grain
Cascara Evacuant	3/4 min.
Fl. Ext. Ipecacuanha...	3/8 min.
Ethylmorphine Hydrochloride	1/32 grain

Supplied in bottles containing 4 oz., 16 oz. and 80 oz. A sample will be supplied on request.

PARKE, DAVIS & CO. [Inc. U.S.A. Limited Ltd.] BEAK STREET, LONDON, W.1.

Laboratories: *Hounslow, Middx.*



D

* *Antiphlogistine applied. Note rapid defervescence. From Case Report—"Indian Med. Gaz.," Mar., 1928.*

The Pneumonias bring fewer cares when Antiphlogistine is applied at the very onset.

ANTIPHLOGISTINE, through its marked decongesting action, will do much to sustain the circulation, relieve dyspnoea, combat the toxemia, promote resolution and assist the patient over the critical period with a minimum of disturbance.

LEWIS'S PUBLICATIONS

READY THIS MONTH. NEW (SECOND) EDITION. With 74 Illustrations on 31 Plates. Demy 8vo. Price 16s. net; postage 9d.

A SHORTER SURGERY A Practical Manual for Senior Students

By R. J. McNEILL LOVE, M.S.Lond., F.R.C.S.Eng., Assistant Surgeon, Metropolitan Hospital; Hunterian Professor, Royal College of Surgeons, etc.

NEARLY READY. With 7 Coloured Plates and 33 other Illustrations. Demy 8vo. Price 10s. 6d. net; postage 6d.

AFFECTIONS OF THE EYE IN GENERAL PRACTICE

By R. LINDSAY REA, M.D., F.R.C.S., Ophthalmic Surgeon to the West End Hospital for Nervous Diseases; Surgeon to the Western Ophthalmic Hosp., etc.

With 50 Illustrations. Crown 8vo. 5s. net; postage 3d.

BRANCHIAL CYSTS

and other Essays on Surgical Subjects in the Facio-Cervical Region.

By HAMILTON BAILEY, F.R.C.S.Eng., Surgeon, Dudley Road Hospital, Birmingham; late Assistant Surgeon, Surgical Registrar and Tutor, Liverpool Royal Infirmary, etc.

"Of definite practical value . . . the present volume is decidedly opportune."—*British Journal of Surgery.*

THIRD Edition. Crown 8vo. 3s. net; postage 4d.

THE CHILD'S DIET

By J. SADLER CURGENVEN, M.R.C.S., L.R.C.P.

"The book is suitable for the use of parents and nurses and is written in simple language."—*British Journal of Children's Diseases.*

With 27 Plates. Demy 8vo. 12s. 6d. net; postage 9d.

THE HISTORY AND TRADITIONS OF THE MOORFIELDS EYE HOSPITAL

One hundred years of Ophthalmic Discovery and Development.

By E. TREACHER COLLINS, F.R.C.S., Consulting Surgeon, Royal London Ophthalmic Hospital and Oxford Eye Hospital, etc.

"This admirable account . . . fascinatingly written . . . well printed, and well illustrated."—BRITISH JOURNAL OF OPHTHALMOLOGY.

With 25 Illustrations, including 17 Plates. 9s. net; postage 5d.

STERILITY IN WOMEN: Diagnosis and Treatment

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. & Edin., Surgeon to the Hospital for Women, Soho Square, London, etc.

"The monograph shows in every page evidence of rich personal experience, and will well repay the most careful study."—*The Lancet.*

EIGHTH Edition. With 2 Plates and 91 other Illustrations. Demy 8vo. 21s. net; postage 9d.

HYGIENE AND PUBLIC HEALTH

(PARKES AND KENWOOD).

Revised by HENRY R. KENWOOD, C.M.G., M.B., F.R.S.Edin., D.P.H.Lond., Emeritus Professor of Hygiene and Public Health in the University of London, etc.; and HAROLD KERR, O.B.E., M.A.Dunelm, M.D.Edin., D.P.H.Camb., Professor of Hygiene and Public Health in the University of Durham, etc.

"Here we have a quarry of concise information valuable to students and practical workers, a bargain at the price asked for it."—*British Medical Journal.*

THIRD Edition. Brought fully up to date and based on Modern Principles. With 52 Plates. Demy 8vo. 35s. net; postage 1s.

THE DERMATERGOSES OR

OCCUPATIONAL AFFECTIONS OF THE SKIN

Giving Descriptions of the Trade Processes, the responsible agents and their actions.

By R. PROSSER WHITE, M.D.Edin., M.R.C.S., President of the Certifying Factory Surgeons' Association; Life Vice-President, Consulting Dermatologist, Royal Albert Edward Infirmary, Wigan; Ex-President of the London Dermatological Society, etc.

"Is not an English, or an Anglo-American work, **it is an international book.**"—*Zentralblatt für Haut und Geschlecht Krankheiten.*

SECOND Edition. Eighth Impression. Post 8vo. 7s. 6d. net; postage 6d.

AEQUANIMITAS:

With other Addresses to Medical Students, Nurses, and Practitioners of Medicine.

By Sir WILLIAM OSLER, Bart., M.D., F.R.S., late Regius Professor of Medicine, University of Oxford, etc.

"Written with all the breadth of view and the beauty of style which make Professor Osler's writings so characteristic and so valuable."—*The Lancet.*

With 32 Illus. in 12 Plates and the Text. Demy 8vo. 6s. net; post. 5d.

THE QUARTZ MERCURY VAPOUR LAMP:

Its Possibilities and Uses in Public Health and General Practice.

By J. BELL FERGUSON, M.D., D.P.H., formerly Medical Officer of Health, Metropolitan Borough of Bethnal Green. With an introduction by Sir HENRY GAUVAIN, M.A., M.D., M.C.

". . . can safely be recommended to anyone . . . clear, concise, and interesting."—*British Medical Journal.*

With 5 Graphic Charts, 16 Plates, and 33 Text Illustrations. Demy 8vo. 10s. 6d. net; postage 6d.

ARTIFICIAL LIGHT TREATMENT OF CHILDREN

In Rickets, Anæmia, and Malnutrition.

By KATHERINE M. L. GAMGEE, M.R.C.S.Eng., D.P.H.Lond.; former Medical Officer-in-Charge, Hull Corporation Artificial Light Clinic, etc. Introduction by Prof. L. HILL, M.B., F.R.S.

"Clearly written, adequately illustrated . . . should well fulfil the purpose for which it was written."—*The Lancet.*

Crown 8vo. 7s. 6d. net; postage 6d.

A MANUAL OF GENERAL MEDICAL PRACTICE

By W. STANLEY SYKES, M.A., M.B., B.Ch.Cantab., D.P.H.Leeds, M.R.C.S.

". . . a readable and competent book—the information has been shrewdly selected with an eye upon practical purposes. This is an interesting and useful little manual."—*The Lancet.*

SECOND Edition. With Illustrations. Crown 8vo. 5s. net; postage 3d.

The CLINICAL EXAMINATION of the LUNGS

By E. M. BROCKBANK, M.D.Vict., F.R.C.P., Hon. Consulting Physician, Royal Infirmary, Manchester; and ALBERT RAMSBOTTOM, M.D.Vict., F.R.C.P., Hon. Physician, Royal Infirmary, Manchester; Lecturer in Clinical Medicine, University of Manchester.

". . . compact little handbook . . . admirably adapted for students."—*British Medical Journal.*

FIFTH Edition. Thoroughly Revised, with Illustrations. Crown 8vo. 6s. 6d. net; postage 5d.

The DIAGNOSIS and TREATMENT of HEART DISEASE

Practical Points for Students and Practitioners.

By E. M. BROCKBANK, M.D.Vict., F.R.C.P., Hon. Physician, Royal Infirmary, Manchester; Lecturer in Clinical Medicine, University of Manchester.

". . . many excellent qualities . . . will be much appreciated."—*British Medical Journal.*

DEMONSTRATIONS OF

PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.Eng., *Surgeon, Dudley Road Hospital, Birmingham.*

The Illustrations form the prominent feature of this volume, and much care has been taken to render them as accurately as possible. They have been still further improved and increased in number for this edition.

Lancet.—"It is time that a book of this nature was available in English. . . . The author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which, in addition to the excellence of reproduction, are informative."

Brit. Jour. Surg.—"An admirable book which we can recommend to all students."

Edin. Med. Jour.—"*We have nothing but praise for this book*, which should be in the hands of every student entering upon his surgical course."

METHODS AND USES OF

HYPNOSIS AND SELF-HYPNOSIS.

By Bernard Hollander, M.D. 6s.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as a survey of all that is scientifically known of this form of psychotherapy.

BY THE SAME AUTHOR.

WITHOUT OFFENCE

Collection of Overdue Accounts on a Commission Basis only.

This question so often arises that we are forced to assume the reason for the frequency with which it occurs is due to to the fact that all dishonest collectors and a great many inefficient Agencies use this method.

We trust that the Medical Profession will pardon us if we make a brief reference to the financial results of their own charges. Medical Practitioners require payment for their services whether their treatment is successful or not; and, generally speaking, they receive payment in full (sooner or later) of 90% of their fees.

We, on the other hand, only receive full payment when we are successful.

No Medical Man would undertake to cure twenty apparently incurable cases on a Commission basis only; but we are frequently requested to do so. ONE-THIRD of the cases sent to us are absolutely hopeless—hence one of our reasons for an Annual Subscription.

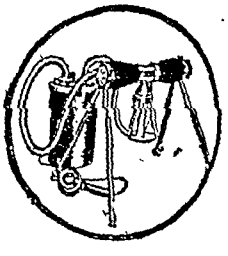
300, HIGH HOLBORN, LONDON, W.C.1.

What do X-rays mean to you?



DO you instinctively think of a room full of mysterious apparatus, crackling sparks and costly equipment? Do you think of years of scientific training, that terrible affliction X-ray dermatitis and the dangers of possible electrocution? Do you think of complicated switchboards, delicate glassware and the weirdness of the effect generally on a nervous patient? Abreast of the times you do not. The dangers have vanished. The difficulties have all been eliminated. That is progress.

Do you ever query why every Hospital now possesses its own X-ray installation? Knowing its importance to the community, you do not. That is merit. To the importance of X-rays in private practice you can also testify.

You will remember your own problem—the numberless instances when, in the interests of your patient and in fairness to yourself, you have felt that a first-class radiograph would have made your diagnosis certain. That is necessity.

The need you have so often felt for something simple, something you could work yourself. In brief, an outfit which, being inexpensive, requires no technical knowledge, can be operated without the slightest element of risk, taken if necessary to the patient's house, and above all will turn out work of the highest quality.

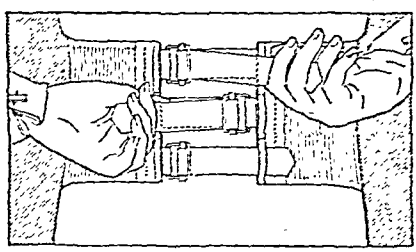
In such a category comes the "METALIX-PORTABLE." We invite you to write for particulars.

PHILIPS LAMPS LTD. (X-RAY DEPT.), PHILIPS HOUSE, 145, CHARING CROSS ROAD, LONDON, W.C.2

THIS NEW *FLEXIBLE* SUPPORT

IS APPROVED BY LEADING SURGICAL OPINION

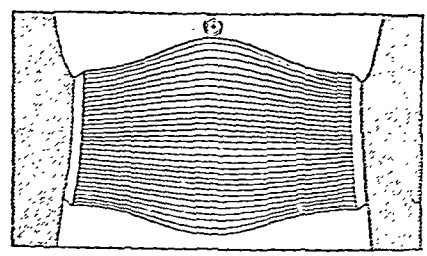
Brit. Pat. No. 279477.



Being Pliable, it Exerts a Firm yet Natural Compression without Restriction

The Linia Belt represents a definite step forward in modern surgical belt construction, and its patented principles are widely approved by leading professional opinion.

This belt, designed by anatomical experts, is the result of 25 years' research and experiment in making elastic supports to medical requirements. The efficiency and comfort of this method of abdominal control is vouched for by the many prominent medical men who have adopted the Linia Belt for their personal use.



THE ACTION OF THE LINIA BELT

The Linia Belt, being made entirely in an exceptionally tough elastic tricot, with firm back and strong extendible front, gives the firm and efficient support so necessary for post-operation wear *without employing any rigid components.* Thus it allows complete freedom in movement and breathing. Corpulence is reduced by a gentle massage action and a *natural* compression exerted which restores any displaced muscles and organs to their natural conformation. Recommended for post-operation wear in cases of Intestinal Ptosis, Enteroptosis, Visceroptosis, Gastroptosis, Nephroptosis.

BACK VIEW.

The tough, live horizontal elastic of this special tricot can be regulated to the required tension by means of slide buckles. Thus its lifting and massaging powers are easily controlled. As the abdomen resumes its normal conformation, further adjustments of the slide buckles can be made.

FRONT VIEW.

At the front of the belt, the thin tricot of great strength can be extended to the required depth, so that a gentle pressure is exerted on the full area of the abdomen.

Pressure is applied from pubis to groins as a safeguard against rupture.

We invite you to submit this belt to your own tests

We shall be pleased to forward a Linia Belt for your inspection free of charge. *POST ORDERS* can be carried out to your direction on receipt of exact measurement round girth and required depth from pubis upwards. Standard depths, 9, 10, and 11 inches. *Prices:* Standard Model, 2½ guineas. In black, thread and elastic, 3 guineas; in pure silk and elastic, 6 guineas. Post free in United Kingdom.

The Linia Belt

is on sale only at

THE DERMASEPTIC QUALITIES OF PEAT

Only during the past 10 or 15 years have the therapeutic qualities contained in peat come to light.

The peat distillate principle is embodied by the makers of Sphagnol in various media. In their ointment, soaps (medical, toilet, and shaving), lotion and suppositories, the strength in all cases being from 5 to 15 per cent., the medium is of the purest quality. The preparations can be purchased at all chemists. The prices are reasonable.

No absurdly extravagant claims are made. The makers simply wish to state that the peat distillate principle is embodied in SPHAGNOL.

Medical practitioners who desire to try this product are invited to send for a trial box of samples.

Intestinal Disinfection

ALIMENTARY TOXÆMIA AND ENDOCRINE INSUFFICIENCY

A WRITER in THE LANCET has directed attention to an apparent connection between alimentary toxæmia and endocrine insufficiency, particularly of the thyroid gland. Many cases of "ill-health," neurasthenia and others, were benefited by the administration of thyroid extract.

He goes on to remark that there seems to be a close connection between endocrine insufficiency and poisoning from intestinal absorption, and notes the beneficial results obtained by the use of intestinal antiseptics in addition in these cases.

He seems to be unaware that the best of all intestinal antiseptics is Kerol. In endocrine insufficiency, therefore, use Kerol in addition to other measures.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

An Improved form of Treatment for Digestive Disorders

"Alocol" is the practitioner's safeguard when alkaline medication is required. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed which, adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

"Alocol" is highly recommended for use in all cases of hyperacidity, against which it is a specific. It is also indicated in the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, etc.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.
